6463. And Vienna also?—I am not absolutely certain about Vienna, but in the municipal return for the year they do not mention that they have found preservatives in the number of milk samples which have been examined, except in one case in which they found sodium carbonate in large quantity.

6464. Do you know if this is a fact in Austria: "Salicylic acid is forbidden in milk, and also other preservatives, such as borax, boracic acid, and soda, the reason presumably being the large amount of milk consumed by invalids and children"—do you know if that is the fact?—Yes, that is what we were given to understand.

6465. (Dr. Tunncliffe.) I should like to ask you if you could tell the Committee how they could get hold of the Denkschrift to which you refer. I take it that the Denkschrift is a resumé of the medical evidence upon the subject?—Yes, you can get the address I think from this journal.

6466. I take it that the bulk of your remarks apply to the milk trade?—Yes, and to the minced meat trade particularly.

6467. Do you know anything about the presence or absence of preservatives in beer?—In Germany that is forbidden, too. There is a law on that subject, I believe.

6468. Is it forbidden in Austria?—Yes.

6469. Is sodium sulphite included in those preservatives which are forbidden in beer?—I do not know whether sodium sulphite is specially mentioned. You see all these cases of sodium sulphite in meat apparently have arisen through a substance which is called "meat preserve crystal," which has had a large sale in Germany, and sodium sulphite, which these butchers—or some butchers at any rate—have been in the habit of adding.

6470. (Chairman.) Did you have any opportunity of

inspecting the milk depôts in Berlin or Vienna?—No, I did not do that.

6471. Are you acquainted with the mode of distribution; can you tell us whether it is in open or closed vessels?—In Berlin it is in closed vessels; there is a big cart with a closed vessel and a tap.

6472. I mean in the sense of being a hermetically sealed vessel; with the tap, of course, it would not be hermetically sealed?—No, there is a tap on the outside.

6473. You do not know whether the system of distributing bottled milk prevails in either of those cities?—No. You can get sterilised milk, but they do not allow boiled milk to be called sterilised milk; it has to be done according to some accepted mode.

6474. "Bottled milk," I said; bottled milk is not necessarily sterilised. In some places the supply is nearly entirely in bottles, but perhaps that you do not know?—I think it is in the smaller towns.

6475. (Dr. Bulstrode.) In Austria did you ascertain anything with regard to the use of saccharin?—No. There was recently published—I do not know whether you saw it—from the German Reichsgesundheitsamt, a "Gutachten" as regards saccharin.

6476. (Chairman.) Have you any general observations you would like to make on the subject?—I should like to say that it seems to me that on general grounds preservatives should be forbidden, because, so far as we know, what is injurious to bacteria is also injurious to the cells of higher developed organisms, and although in the latter case they are capable of being replaced, which the bacteria would not be, nevertheless it does not seem to me that the highly developed organism should be called upon to replace cells which have been destroyed by disinfectants.

6477. Does your objection to the use of preservatives extend to other substances besides milk?—Yes, it certainly would, for instance, in the case of sodium sulphite, and it seems to me it should do also in the case of boric acid; borax I am not so certain about. You see, the addition of preservatives, as has been pointed out, I believe, before this Committee, only harms the putrefactive organisms, whilst it does not really usually attack the more potent pathogenic organisms, so that they still remain effective, while you have simply destroyed the putrefactive organisms. I think altogether we ought to aim really the same way as in surgery, where instead of antiseptic you aim at aseptic surgery. So in the same way we ought to aim at aseptic rather than antiseptic food. So far as one can find out, apparently the difficulty is merely one of expense. In Germany the milk is transferred in railway vans, which are cooled by ice, and there does not seem any very good reason why that should not be the case here. In fact, ice is apparently used in England to a much less extent than it might be. As to the interference with trade, judging from other things in Germany on what was more particularly relevant to our inquiry, for instance, the question where manufacturers had to dispose of their own waste we found that although they were put to considerable expense in doing that, nevertheless, so far as we could ascertain, it did not hurt the trade. They were enterprising enough to keep on at their trade in spite of these extra expenses. I suppose that if the German manufacturer and merchant can do that we ought to be able to do it here.

6478. Do you look upon it as established that putrefactive micro-organisms are generally of a lower vitality than pathogenic organisms?—Some of them certainly are. I was thinking more particularly of a spore-bearing pathogenic organism, which most of the putrefactive ones are not. The great objection, however, seems to me that we have not got any antiseptic that we know which is injurious and will touch bacteria which will not also injure living cells.

6479. And in some instances affect the digestibility of the food by hardening it. Is that not so?—Yes. It does not apparently—not, at any rate, in the doses used—affect the ferments themselves; in fact, in doing experiments on digestion one sometimes adds an antiseptic in order to prevent putrefaction; but that is quite a different thing to affecting the cells which produce the ferments.

6480. In the event of the use of some or all preservatives being sanctioned, would you think any advantage would be gained by a notification of the presence of these preservatives accompanying the article?—I should say so, certainly. One always prefers to know what one is having, and a doctor who may be prescribing the same.

sort of thing would like to know what dose his patient is taking.

6481. (*Dr. Bulstrode.*) You are a physiologist; I take it?—Yes.

6482. Might I ask you what value you as a physiologist think on general principles is to be attached to experiments made upon the lower animals in regard to conclusions as to the effect of preservatives?—It is necessary, of course, to get comparable results, and for that purpose one must have animals in the same stage; and animals, I think they ought to be, whose digestions are somewhat similar. I do not think there can be much good, for instance, in making experiments on herbivorous animals and then trying to compare the results which you obtain on man. Again it is not any good making experiments on full-grown animals if you wish to draw deductions as to the effects on infants. But as a whole I think one can draw a fair inference. I should prefer, for instance, to make experiments on monkeys rather than on cats or dogs, but nevertheless I think from experiments on cats and dogs, provided they are in a similar stage of growth, you can draw a fair inference as to what the result is likely to be on man; only I do think that animals seem to stand what one might call unnatural food, or at any rate unnatural additions to food as a whole, weight for weight and age for age, better than human beings.

6483. Would you make that remark with regard to monkeys as well; would you put monkeys in that group?—No, because I have not any pharmacological experience

of monkeys; I have not experimented on them with drugs.

6484. (*Chairman.*) Would you say that the idiosyncrasies of man are nearer to those of a pig than to those of a cat?—That I really do not know about. I know it is alleged that the pig in structure resembles man more nearly than some other animals, but I have no definite knowledge about that.

6485. He is more like a man in his general food, is he not?—I hope not.

6486. He is omnivorous?—Do you mean in regard to his digestion?

6487. What I mean is that a man is less purely carnivorous than a cat, and is omnivorous like a swine?—Yes, but still I think the pig takes a good many more bacteria into his inside.

6488. (*Dr. Tunncliffe.*) I take it from what you have said just now in reply to Dr. Bulstrode that you would think that one would be justified in deducing a positive result from animals to man, but not a negative one?—That is so.

6489. That expresses your opinion, I think, more clearly than it was expressed before—you understand what I mean; if you get a positive result you would be practically certain you would have a positive result in man, but if you get a negative result it would not follow?—With regard to preservatives?

6490. With regard to preservatives?—Yes.

*Dr. A. Grünbaum.*

7 Feb. 1900.

## TWENTY-SECOND DAY.

*Friday, 9th February, 1900*

### PRESENT :

The Right Hon. Sir HERBERT MAXWELL, Bart., M.P., F.R.S. (*Chairman*).

H. TIMBRELL BULSTRODE, Esq., M.D.

F. W. TUNNICLIFFE, Esq., M.D.

CHARLES J. HUDDART, Esq., *Secretary*.

Professor JOHN ATTFIELD, called ; and Examined.

*Prof. J. Attfield.*

9 Feb. 1900

6491. (*Chairman.*) You are a Doctor of Philosophy and a Fellow of the Royal Society, are you not?—Yes.

6492. You have been for thirty-four years Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain?—Yes, from 1862 to 1895.

6493. You are the author of a manual on general medical and pharmaceutical chemistry?—That is so, seventeen editions, I may say.

6494. And also editor of the "British Pharmacopoeia"?—Yes.

6495. I understand that you are prepared to lay before the Committee the results of certain observations made by you as to the action on the human subject of some of the modern preservatives used in food?—Yes, I am.

6496. Will you kindly tell us what you can?—The experience that I have to lay before the Committee relates, of course, partly to my professional knowledge as a scientific chemist. But I suppose that my chief qualification for appearing before the Committee is that personally I have been for many years what is termed a dyspeptic—I have been very dyspeptic—and have brought all the knowledge I have of chemistry to bear upon the matter with a view to my relief—as would be natural enough. Considering that the digestive processes are nearly all chemical processes, I thought that I could, perhaps, save myself much trouble and discomfort and pain; and I have succeeded. Still, I have acted under due medical and surgical direction. I perhaps ought to have mentioned that first, in order that it may be seen that I have not been simply adopting some amateur experiments. I have acted under the direction of the late Sir William Savory, the eminent surgeon, who was a very old friend of mine; he and I

were demonstrators at St. Bartholomew's Hospital together, and he has kindly been my friend in this personal matter as well as in many other directions. He it was who at first advised me to use antiseptics to prevent that unnatural decomposition of food in the stomach which gives rise to gas, and therefore to distention, and therefore to discomfort and even pain. He recommended me to use various antiseptics. Then, too, the late Dr. Habershon, who was a great authority on dyspepsia, also recommended me to use antiseptics, and Doctor, now Sir Thomas, Lauder Brunton, and also Sir Richard Quain, with whom I was associated in connection with the "British Pharmacopoeia," he being the President of the Medical Council. So that I have acted under proper advice. The antiseptics that I have used under this advice have been carbolic acid and sulphurous acid taken in the form of sodium thiosulphate, commonly called sodium hyposulphite, creosote, and boric acid. I do not know whether it would be interesting to the Committee, having regard to their Terms of Reference, to give the doses?

6497. In the case of boric acid it would be so?—Then the quantity of boric acid has been from 10 to 15 grains three times daily. By way of experiment I have taken very much larger quantities; but that has been found to be sufficient to prevent this unnatural, abnormal decomposition of food in the stomach to which I have alluded, and which appears to me to be due simply to ordinary natural causes—that is to say, to food kept at high temperature in a moist place, and there for a much longer time in the case of an invalid, a dyspeptic—than it would be in the case of a healthy person. I have got abundance of experimental evidence to show that food has commonly remained in my own

Prof. J.  
Attfield.

9 Feb. 1900.

stomach not for the ordinary period which commonly separates meals, four hours or so, but for eight hours and much longer. In the case of some uncooked fibrous foods, which can easily be traced by the eye when you see the contents of the stomach—such, for instance, as the skins of black grapes—they will remain for a week or ten days, in small quantities, of course, a few just hidden up, I suppose in the coats of the stomach, or still more likely, getting to the bottom of the stomach. I can give experimental evidence of that too. Those things are not digested in the ordinary period of four or five hours that separates meals, but take a much longer time. It is such fibrous articles, chiefly vegetable fibres, such as the fibres of cabbages, sprouts, celery, and so on, that remain in the stomach, according to my observations of the washings out of the stomach, that take so long to digest, and that are liable to ferment, and it is this fermentation, resulting in gas, which boric acid prevents in the doses that I have mentioned.

6498. The aggregate daily dose being between 30 and 45 grains?—That would be so. I have taken double that for that matter, but that would be the common quantity. I have generally found 10 grains sufficient to prevent the decomposition.

6499. (*Dr. Tunncliffe.*) Three times a day?—Yes; I have taken as much as 60 or 70 grains in the day, but only for experimental purposes.

6500. (*Chairman.*) Have you ever found any inconvenience arise?—No. I have taken the larger quantities latterly, since the question of food preservatives has come up. I was rather anxious to know how much one could stand, and what the effect would be. I have taken a large quantity like that, and I never could detect any influence harmful. A far smaller quantity, namely, 10 grains, has always seemed to me to be sufficient to prevent the fermentative decomposition that I have spoken of; but I have taken 30 or 40 grains at a time, and those quantities did just as much work, I need not say, as the 10 grains, but nothing more. I never could detect any inconvenience whatever of any kind.

6501. Boric acid is voided through the kidneys, is it not?—Yes, I believe it is.

6502. You can assign no limit to the amount which can be got rid of in the day?—No, I have never made any other special experiments than those I have mentioned to the Committee. My plan of taking that particular antiseptic, boric acid, has been now for some years by, so to speak, peppering it on to green vegetable food from a castor. I have generally had a little castor (like this) by the side of my plate. Inasmuch as I rarely needed to take antiseptics for meat or anything of that kind, it has seemed most simple to just pepper it on, to green vegetable food especially. I perhaps ought to say that I have never found any discomfort from starchy food such as bread or potatoes—not the slightest; but fibrous food, or what the chemist would call cellulosic food—that is to say, the cellulose rather than the starch of vegetable food, is what the stomach, in my case, seemed to have a great difficulty in dealing with and breaking down. I may say that my proof of that is that, having, by the advice of these surgeons and physicians, and of my family medical adviser, Dr. Haycraft Berry, some ten years ago, adopted another plan altogether, namely, at the end of four or five hours, when it may be assumed food ought to have digested, and that any food then remaining is liable to decompose—then swallowing an ordinary stomach tube, pouring warm water down the tube, and then turning the outer flexible portion down the other way, and so converting it into a siphon, and running off the residual contents of the stomach. Doing that two or three times over, perhaps, one in that way removes all the residual food which, presumably, is not going to do one any good, however one may persevere, but rather harm. Washing out that residual food, then I should have the chance, you see, of examining that food, and, being a chemist and a microscopist, and accustomed all my professional life to observe accurately, I could see what length of time was necessary for various kinds of food to digest—which would digest in reasonable time, and which would not.

6503. Some kinds of food you found little or no difficulty in dealing with?—Yes, that is so.

6504. Do you find their digestibility affected by the boric acid?—No, not in the slightest—no matter what quantity of boric acid I might take or might not take. I have always found that starchy food digests within four or five hours if it is only in a proper condition. But if it is uncooked starch, and especially if it is in a

clammy condition, as new bread, for instance, which is proverbially indigestible, then there is a different result. What I mean is, that the mechanical condition of the starch has, it seems to me, a very great deal to do with it. Rice grains not very thoroughly cooked, to a pulp, for instance, are liable to remain undigested after a reasonable time; certainly new bread, imperfectly cooked bread, will remain in that way; so will anything which is not only fibrous, not only hard, but is in a close, clammy condition.

6505. Such as the man in the street would recognise as indigestible?—Yes, precisely; these things do not digest, however soft they may be, the work of digestion does not go on. Lumps of sweetbread are troublesome, not but what they are soft, as everybody knows, and very nice if properly cooked, but, nevertheless, there is a difficulty in getting rid of clammy lumps. I have peppered sweetbread with boric acid so as to keep it from fermenting, and in this way I have been able no doubt to digest it when I could not if I did not take boric acid.

6506. You mean that the boric acid enables you to retain it long enough in the stomach without septic fermentation proceeding, and therefore your digestion is enabled to deal with it?—Slowly to deal with it, that is so.

6507. (*Dr. Bulstrode.*) Your evidence would tend to show that in your case the amount of boric acid which you have been accustomed to take does produce an inhibiting action upon certain putrefactive bacteria—would that not be so?—Yes, I suppose so. I am not an actual bacteriologist, although I have to do something in that way, but I should certainly come to that conclusion.

6508. Therefore, that amount of boric acid which you took may be held to have a very considerable influence upon vegetable cells?—That I do not know. I do not see where the inference comes in there. Whether I take boric acid or no, unfortunately these fibrous vegetable structures or fibres remain there, and do not digest—they do not get worked up to a pulp.

6509. The inference is that the operations of certain bacteria are inhibited, is it not?—Yes, that appears to be so, certain kinds of bacteria.

6510. Are we to take it that formerly you used to wash out your stomach?—I have washed out my stomach for ten years.

6511. You do not do it now?—Not so much for dyspepsia, for of serious dyspepsia I am now cured, but once now and then if I have by accident taken some undesirable food, or perhaps taken a little too much—I mean too much for any weak gastric organ, then such a sense of irritation comes about that one washes out.

6512. I do not quite understand the relation between this washing out and the boric acid?—Whether I have taken boric acid or not, the washings show on examination that boric acid has no influence apparently upon them so far as digestion is concerned. It does prevent the abnormal changes which result in gas and uncomfortable distension of the gastric walls and pain, it does not prevent the natural changes which result in satisfactory digestion.

6513. Of course, you only add the boric acid at the moment when you are about to take the food?—I have commonly done that. Years ago—I forget now who advised me—I used to take 10 grains two hours after a meal. I did it, of course, being loyal to my adviser, but after a bit, when I got a little more knowledge about the matter, and could see which kinds of food were indigestible and which not, then, as a chemist, it struck me that the best thing to do would be to put boric acid on the indigestible kinds of food on one's plate. That is how I adopted that plan.

6514. I mean probably there would not be an opportunity for any effect to be produced upon the food by the action of the boric acids which you use?—No, not before eating.

6515. So that really what your evidence would come to is that in the specific condition of dyspepsia from which you suffered you found boric acid taken with certain forms of food prevented this dyspepsia or minimised it?—That is so. Then there is the further inference to which I alluded just now. The further inference I make is that inasmuch as I get a similar appearance of the particles of food as washed out of the stomach whether I have taken boric acid or not; therefore, the boric acid does not apparently at all prevent those articles of food from being digested.

6516. I think you say in your synopsis that you have made some bacteriological investigations with regard to the washings out?—No, I said I was not a bacteriologist, but, in fact, my son is.

Prof. J.  
Attfield.

9 Feb. 1900.

6517. Has your son helped you in this?—Yes.

6518. It would be very interesting to know bacteriologically to what the observations upon cultivations from the washings out have led?—That I can tell you—more or less second hand, of course. My son made a number of experiments on the washings running over some months, and he seemed finally to come to this conclusion that there was nothing much to be learnt by the bacteriological examination. What was perfectly obvious was that there was an abundance of *sarcinæ ventriculi* produced; there were myriads of those curious little bale-shaped particles.

6519. Did he make no cultivations on nutrient media from the washed out substance?—Not many, because he did not feel inclined to carry on the examination. As regards the *sarcinæ*, he said there was nothing much further to learn about them, and as regards other things he tried a few experiments on cultivations, and could make nothing of them having personal or public interest.

6520. In your synopsis you say, "I am aware that salted and smoked food is said to digest relatively slowly, and it does, but not more slowly, I find, than all tissue-hardened food; the retardation is not due to the antiseptics?"—Yes, I have come to that conclusion.

6521. But some of those antiseptics are distinctly hardening agents—formalin, for instance?—That is so. I do not know anything by personal experience dietetically about formalin, as I never took any formalin.

6522. I mean that any conceivable food which has been kept by formalin might be in such a hardened condition that it in itself might have produced retardation of digestion, might it not?—I think that is quite possible. I know a great deal about formalin and its action upon albuminoid substances.

6523. You do?—Yes, I do, but not dietetically, as I have never taken anything preserved by formalin.

6524. (Chairman.) Not consciously?—Not consciously.

6525. (Dr. Bulstrode.) Could you tell us what you know of the action of formalin?—I have had to examine its action on plates of gelatin which have hardened to such an extent that they can be used for wall covering, for instance.

6526. In what strength was the formalin which you are now speaking of?—I do not remember the strength, but it would be very strong, of course—quite beyond the range of any food or anything of that kind.

6527. Could you not give an approximate idea? Where did you get the formalin from?—I could tell you by reference to my memoranda—I think I could give actual figures and so on. This was a matter in which I was consulted by some folks who wanted to support an inventor in producing formalin-hardened gelatin for general use for many purposes. They got as far as this, that very thin plates—extremely thin plates—thus hardened could be used for making coloured bags for sweetmeats. You see, such plates would look very pretty, and confectioners found that there would be a great demand for the sweets that they put into such little bags as that; and, in fact, I believe the article is sold very largely to this day. There was a hope that something could be produced that would almost supersede leather by pushing the action, but when I was engaged in the matter I found that could not very well be done.

6528. How long was this ago that you are speaking of now?—I should think about three years perhaps.

6529. Three years ago?—Two to three years ago.

6530. Where did you procure the formalin which you experimented with?—I got some from wholesale druggists for the experiments I made myself. It was a wholesale firm in the City.

6531. Do you know what the composition of the formalin was?—It was, I think, the ordinary aqueous 40 per cent. article; that is 40 per cent. of formic aldehyde.

6532. You had a great deal to do with the "British Pharmacopœia," I think?—Yes, I have been the editor; I am the editor of the present "Pharmacopœia" for the Medical Council.

6533. Is it the fact that in the last edition the dose of boric acid was diminished from 10 to 30 grains to from 5 to 15 grains?—Yes, it was diminished as compared with the dose mentioned in the previous "Pharmacopœia" of 1885, that is from "5 to 30 grains" to "5 to 15 grains."

6534. Could you tell the Committee why that was done?—Simply because it was found by the experience of all the members of the Pharmacopœia Committee (and my own personal experience) that in the case of that particular

drug 5 to 15 grains would do everything that 10 to 30 grains would do. That was the only reason.

6535. Are we right in inferring that 10 to 30 grains would do more than from 5 to 15?—That is not so.

6536. Would do no more?—Medicinally they would do no more. Having in view the quantity of material in the stomach, for instance—I am speaking now of matters that I know about myself—5 to 15 grains there would be ample, and to put in 10 to 30 would be useless. I tried it up to 60, and I could not get any better effect, if I may say so, from the point of view of discomfort, with 30 to 60 grains than I could with 5 to 15.

6537. You took 30 to 60 three times a day, did you?—No, I did not. On one occasion I took 50 grains twice in the day.

6538. You did not keep that up at all?—No, I did not. I have kept up above 30 grains, that is to say, 15 grains three times a day week after week, which is a total of 45 grains daily.

6539. (Dr. Tunncliffe.) I think you said that you had taken some preservative which would at any rate be practically the same thing as sodium hyposulphite?—Yes, the sodium hyposulphite would yield sulphurous acid.

6540. That would act in the same manner as sodium hyposulphite in beer then from the chemico-biological standpoint?—No doubt it would. Yielding, as it does, sulphurous acid, it was a very convenient way of taking sulphurous acid. That was by Dr. Habershon's suggestion. I produce his prescription.

6541. Therefore your experiences that you were telling the Committee of in this regard would have relation to the use of sodium hyposulphite as a food preservative or as beer preservative?—Yes, I think so. That was Dr. Habershon's favourite prescription he told me.

6542. Would you tell the Committee shortly what your experiences were with the equivalent of sodium hyposulphite?—I found it quite prevented—

6543. The dose please first that you took?—The dose was that you see mentioned in Dr. Habershon's prescription, namely, 15 grains from once to three times a day. I found that in those quantities it quite prevented the decomposition to which I have referred, that is the production of gas, distention, discomfort, and pain. But when there were eructations there was an unpleasant flavour, and odour, of sulphurous acid, which does not attach to boric acid. I think that would be my personal chief objection to sodium hyposulphite.

6544. More especially I should like to ask you with regard to whether you noticed that it also had practically no effect upon the digestive processes in so far as you were concerned?—I cannot fully answer that question, because when I took sodium hyposulphite it would be five or six years before I adopted the use of the ordinary washing tube to which I have referred.

6545. So, therefore, your experiences on this head are not so valuable as the former ones?—No, they are not. I have tried it once or twice since, as a matter of experiment. I have taken two or three doses of the hyposulphite, and then examined the washings. I could not find any difference, but then that was only a two or three days' experience, whereas my experience of boric acid runs over some years, and to hundreds of experiments.

6546. We have had it in evidence repeatedly before this Committee that it is improbable that if a substance exerts an inhibitory action upon the bacteria causing decomposition, it will not exert the same, or, at any rate, a very similar action, upon the digestive enzymes; do you agree with that statement?—That seems to me to be a most reasonable inference, but it does not accord with my experience, it is not true in my judgment.

6547. (Chairman.) I would like to ask you whether you are prepared to give any general opinion as to the necessity for regulating the use of these preservatives in food?—I naturally have had opinions on the matter, for I have been consulted in many of these cases that have been brought before the courts, but I do not think my opinion is of any particular value on matters of that kind. I only have the experience of a chemist and an analyst and of a consultant who is appealed to by parties in actions.

6548. As a citizen, as a consumer who has devoted some attention to the subject, and who is acquainted with the nature of the substances used, do you think that their presence ought to be notified, and that the consumer ought to be aware of what he is taking?—In the abstract I should say yes to that. I think he should, so far as that can be done. I see no objection to the principle,

Prof. J.  
Attfield.

9 Feb. 1900.

but I do not quite see how it is to be carried out. I should rather support the indication on labels of things that are contained in metal or other cases—as to what such-and-such a thing has been preserved by. Of course, the Committee will see that from my experience I have no more objection to boric acid, for instance, than to salt, but I think it is quite reasonable that if an article has been prepared with salt, that might be stated on the label, and if prepared with boric acid that might be stated on the label. I should see no difficulty, so far as labelling is concerned. It is only when you come to selling things retail that I see a difficulty. Take, for example, a ham and beef shop; a quarter of a pound of beef and two ounces of ham, so I am told, is a very common order; I do not know whether you are to wrap that in paper with a label on it or something; I do not see how it is to be done effectively.

6549. Salt is itself a food, is it not?—Well, I do not know. I have often thought about that matter. I do not see why it is any more a food than boric acid would be. It is true it is an article that everybody is accustomed to, but I have often speculated as to why one should take salt. A friend of mine, a consulting engineer, never takes any.

6550. It is one of the components of the human body?—Yes, I know, and, of course, there would be something in that. On the other hand, boric acid is found, though of course to a minute extent, in many vegetables; it has been found in wines and in the hop plant, and therefore in beer, but in minute amounts. I do not mean to say that there is any quantitative parallel to be drawn between that and salt.

6551. Is not the great difference between such a preservative as salt and such a preservative as boric acid that salt announces its own presence?—Yes, because apparently you have to use a large quantity of salt as compared with the quantity of boric acid; and then comes in the natural flavour of the salt—you can detect it by its flavour and you cannot detect boric acid by its flavour because it has no flavour.

6552. I will put this further question to you: You, as an adult, find no inconvenience from the use of boric acid in considerable quantities and regularly; is it not conceivable that an infant fed entirely on milk preserved with boric acid might suffer some serious consequences?—In answer to the question is it conceivable? I say yes directly; but there I can give no experience to the Committee, of course, except hearsay experience. I think that there was a gentleman from Glasgow before the Committee, Dr. Bell, whom I once met in a case in Wales, in connection with this question; he assured me—and I may refer to it, although again it is secondhand, because I am sure he must have mentioned it to the Committee, if he has been before the Committee—that his own children, when quite children, had milk given to them day after day in large quantities with boric acid in it. That is really the only answer I can make.

6553. "When quite children" is rather vague, is it not?—Yes.

6554. I spoke of infants?—I had the impression from him that he began with them as infants to give them milk with boric acid. He had a great idea of the value of milk, and his notion was to keep the milk so that he could give it to them in the summer, for instance, at any time in the day. They had big lots of milk, and, as a matter of course, he spoke of their fine appearance, their growth, and their general thriving condition.

6555. It is not every infant who would stand treating with salted milk, is it?—I do not know much about these matters, but I take it that it is a question of quantity.

6556. And that would be the case with boric acid also?—I should think so.

6557. It is desirable to know what quantity of this drug is being consumed in the food?—Yes, I should think so; I should think that is only fair and right—I should like to know it myself.

6558. But you do not attach great importance to it?—No, not great importance. There, I think, *caveat emptor* begins to apply. Persons taking food, as they do several times a day, every day of their lives, ought reasonably to be expected to have some knowledge even gained by their daily experience; and, secondly, I take it that manufacturers who use these things would rather want to preserve the lives and health of their customers than to damage them—there again would come in some sort of a guarantee. But really these are only my own speculations, and I do not pretend to be an authority.

6559. Is it not rather straining the adage to apply *caveat emptor* to an infant?—Yes, and I did not mean to do that for a moment. I was only alluding to adults and persons who had to buy—which infants have not.

6560. (Dr. Bulstrode.) May we take it that you, having a great deal to do with the British Pharmacopoeia, and having regard to the fact that the pharmacopoeal dose for an adult is 5 to 15 grains, see no public danger in the use of milk for quite infants having as much as 80 grains a pint of boric acid in it?—Eighty grains to the pint, is that not a large quantity?

6561. Very, according to the dose put down by the British Pharmacopoeia?—80 grains to the pint is beyond me; I know nothing about the matter from that point of view, but it strikes me as being a very large quantity.

6562. If I tell you, as a fact, that we have had evidence before us that that has been found, do you see in that any reason why the apparently indiscriminate use of boric acid should be stopped?—Yes, I would, if that were not an isolated case. It seems to me that that is like taking tablespoonfuls of salt.

6563. If that is possible—and we have had evidence of doses far larger than the British Pharmacopoeia lays down (it is almost, perhaps, an everyday occurrence, certainly for infants), would that modify your opinion at all?—Do I really understand that infants might take much larger doses than those indicated in the Pharmacopoeia—that is to say, 5 to 15 grains?

6564. Far greater?—Per day?

6565. Per day?—My common sense tells me that I must hesitate before agreeing with the giving of such quantities, certainly. I should want some more evidence on that allegation as regards every-day experience.

6566. One more point. Take the case of formalin; you have told us that formalin, as we have been told before, is a very active hardening agent?—Yes.

6567. Do you see any objection to the indiscriminate use of formalin in foods intended for infants and invalids?—I certainly see objection to the indiscriminate use of it, but I want to know more about it. I should infer, from what I do know of the action of antiseptics, that a certain quantity, I do not know how much, a minute quantity very likely, in food would preserve the food outside the body, but when you take it into the stomach it would cease to have any action whatever. That would be my inference from my own experiments on other antiseptics, but I know nothing directly about the action of formalin as a constituent of food.

6568. (Chairman.) You have not told us anything about salicylic acid. I do not know whether you have had any experience of it?—I do not know much about salicylic acid. I have taken it, and I know it is consumed in large quantities. So far as my experience goes, which has simply been experimental, salicylic acid may be taken in quantities of from 5 to 15 grains at a time without retarding the digestive processes.

6569. The question of idiosyncrasy comes in, does it not, in these matters?—Yes, I dare say, and that is why I was so anxious at the beginning to tell the Committee that my experience was simply personal. It is the experience of one individual, but that individual happens to be a scientific chemist, and these are mostly chemical questions; that really is my most important qualification for appearing before the Committee.

6570. You have given some attention to colouring matters in food, I think?—I have the ordinary experience of a chemist who is applied to by firms for advice and that kind of thing.

6571. Have you become aware of any hurtful agents used in colouring matters?—No, I have not. The question that has commonly been put to me by wholesale confectioners has been—is this colouring matter of which we show you a sample injurious to health? Up to ten years ago I had always answered that question in this way—I am not qualified to form an opinion; but since I have used the stomach tube I have endeavoured to answer the question by the simple method of taking quantities of the colouring matter, and I have never come across a colouring matter that was injurious, that was distinctly harmful, and that distinctly produced any discomfort in any way. That is all I can say. But, unless I have known the source of the colouring matter and something about it, I have commonly refused to entertain the question.

6572. There are some substances which are used which

are admittedly harmful if they are taken in sufficient quantities—is that not common knowledge?—That is so, of course.

6573. Sulphate of copper, for instance?—I have had some experience of that question of copper in vegetables, though I do not know whether it would be of any use to the Committee. I have been the chemical adviser of a very large firm indeed of wholesale canners of food, and bottlers of food, and preservers of food—people who make jams, pickles, and so on. That firm has put that question to me on some occasions because they have had to import vegetables, chiefly French things—French pickles highly coloured—and they objected to what they call handle them at all—that is to have anything to do with their sale unless they were either free from copper or contained such a minute amount as to be harmless. So I have examined such articles from time to time. I never could find more than a trace of copper in such vegetables, and, indeed, from my professional experience I may say that that copper seems to get in by manipulating the vegetables in copper vessels. I have never yet come across a good case where copper has been intentionally added in order to colour vegetables. It has seemed to me that a minute amount of copper seems to act as a sort of mordant, and to maintain and preserve the chlorophyll or other green matter of vegetables, and that the quantity is excessively

minute. In connection with the firm I have mentioned they never used any copper in any way—I mean never added any copper sulphate to colour or anything of that kind, but they, like, I think, all other such firms, have commonly used copper vessels in making jam, for instance. Some fruit juices are acid, and I have wondered whether such preserved fruits would, if examined in considerable quantities, show the presence of copper. I have examined a hundred grammes at a time of such fruits, and got the ash and examined that for copper, and I have only once detected copper in the course of three or four years, examining such jams, perhaps, twice a year. There was a very minute amount, but still I did find it, and so I went into the question. So far as I could ascertain by inquiries in the firm a man had been careless in not cleaning his copper steam pans, and in the upper part—not in the lower part, where the juice boiling with sugar was going on, but in the upper part—there would be a greenness, you know, and I take it some soluble salt of copper formed, and that would have got dissolved, but even in that case the quantity was extremely minute, quite a harmless amount. However, ever after that in my inspection of this particular factory, which I do to this day and have done for twenty years—six times a year, every two months—I have been very careful to look after the copper pans, and I do not detect any copper in the jams.

*Prof. J. Attfield.*

9 Feb. 1900.

Mr. CHARLES WALWYN RADCLIFFE-COOKE, M.P., called; and Examined.

*Mr. C. W. Radcliffe-Cooke, M.P.*

6574. (*Chairman.*) As we know, you are a Member of Parliament?—Yes.

6575. And you are a maker of cider and perry?—Yes.

6576. I think you are prepared to tell the Committee something about the necessity for the use of preservatives which we understand are used in such manufactures?—Or rather their not being necessary—perhaps that would put it better. I have had cider made on my place, according to the records, for 200 years. My father made and sold cider before me, and I have always made cider, and I now make it on a fairly good scale—from 15,000 to 20,000 gallons yearly, or something like that. I have never found it necessary to use a preservative, nor have I heard that any kind of preservative was ever used in the making of cider and perry on my estate. Of course, the Committee know how cider and perry are made. The juice is expressed from the fruit in a mill, either one of the old stone mills—I have several—or in a machine like a turnip-cutter, in which the fruit is cut up and passed through rollers, and the pulp afterwards put in a press and the juice expressed, and pumped at once into proper vessels—large vats. At the time of doing this the juice is tested with the saccharometer or with the hydrometer in order to ascertain the density of it. After a time the first fermentation begins forming a crust at the top and lees at the bottom, while the liquor between becomes comparatively clear. It is then tested again to see what sweetness it has lost during the course of fermentation, and is racked into other vessels, and from time to time this racking goes on until the liquor becomes comparatively bright. But if you want it for bottling you must filter it afterwards, and either pass it through a German filter, which contains compressed cotton pulp, forcing it through by a pump, or else by gravitation, according to your appliances, and that renders it perfectly bright. But at the same time that extracts a great many of the germs of fermentation. I have tried it myself, and found that occasionally the cider will not come up afterwards—it did not last year, for instance—I suppose all the ferment germs were extracted. The process that I adopt (which is a very old process) is that of running it through bags, like large jelly bags, made of a kind of linen stuff, which I think they call Forfar. This is called dropping the cider or perry. These bags are placed in a frame, so fixed that they all run together, and then the juice comes out and is put quite bright into a vessel. Then that vessel is properly stopped down, and attention is paid from time to time, by testing it, to see how the fermentation is going on, and if the fermentation is going on too rapidly removing it from that into another vessel, which for precautions sake you may sulphur—because the vessel may not be quite clean, even with the utmost efforts—so it is desirable to burn a sulphur match in the vessel, before putting the cider or perry into it. If this is done carefully and with attention there is no necessity to do anything else whatever to it. I should say, however, that before

filtering the cider in these bags, or passing through this (Lumley's) filter, it is desirable to put some albuminous substance in the cider in order that it may not run too quickly through the bags or through the filter. The albuminous substance that I use is skim milk—about a gallon to a hogshead—our hogsheads running to about 100 gallons, and this is well stirred up. Then it runs much brighter than it otherwise would do. With cider so treated in that way, in perfectly clean vessels, the mill perfectly clean, the vessels perfectly cleaned out, everyone of them washed out, scalded, scoured, fumigated, if necessary, with sulphur—there is nothing else that need be done to either cider or perry.

6577. What is fumigation for?—To destroy any bad germs just as you would fumigate a room if you had the germs of disease in it, so you would fumigate the vessels for the purpose of destroying bad germs. Germs being everywhere in the atmosphere, as we all know, there may be some bad germs about, and you want to have your vessel perfectly free from them. Fumigation also has some effect in stopping the fermentation in the liquor, because, I believe, although I am not a chemist, that it forms something like sulphur dioxide, and ultimately sulphuric acid, and that has an effect upon the cider itself, but not a very great effect; at any rate I have not found it to have a great effect. It cleans the vessels, but has not a very great effect in stopping fermentation. If that is done, and if the fruit is fairly clean and rotten fruit removed there is nothing else that need be done to the cider, and whether it is good or bad cider, or poor or weak cider, will depend more or less upon the quality of the fruit.

6578. May we assume that some manufacturers use preservatives?—Yes, a good many do, but, of course, you will not ask me to mention the names of any?

6579. Certainly not?—Being a cider maker myself, people would say that I disclosed certain practices for my own benefit, or something like that. The preservatives are those with which this Committee is perfectly familiar—they are nearly all preparations either of borax or salicylic acid.

6580. At what period of the manufacture—at what stage—are preservatives added?—They are put in at any time, but what they put them in for is generally to affect fermentation. The first that I have on my list is sugar of boron. I do not know what particular derivative of borax that is, but no doubt it is the same as the others in its effect. I find here that a great deal of this is also used by mineral water companies. The Dorset Mineral Water Company, for example, say: "It is, we may say, exceptionally useful for keeping good and bright all non-alcoholic beverages which we have previously had considerable trouble with." Here is a testimonial from a cider maker: "Please send me one of the original cases of 'sugar of boron' (56 lbs). The bottled cider and perry I treated with it last November is in splendid condition and quite free from deposit"—that is because the fermentation is stopped. Of course, as the Committee

Mr. C. W.  
Radcliffe-  
Cooke, M.P.  
—  
9 Feb. 1900.

know perfectly well, all liquors in fermentation throw down a certain amount of deposit, and the modern sellers and also buyers of cider and perry want to have something perfectly clear, so that they can turn the bottle upside down without finding the slightest sediment in it. In order to produce that result they stop the fermentation, and, of course, stop the liquor from maturing and becoming wholesome. I find among the testimonials I have here that the French Vintage Company of Mont-le-Grand, Exeter, say—these are all printed, so, of course, they may appear—"Dear Sirs,—Please send me at once another 14 lb. case of your 'Boron,' which we find very useful for our high-class champagne cider.—Yours faithfully, (signed) J. Clarke, manager."

6581. (*Dr. Tunncliffe.*) Is that a testimonial?—These are from testimonials sent out by the sellers of sugar of boron, so, of course, they are public property. This was sent to me by somebody, I forget by whom now. It is also used a great deal in brewing. The Albion Brewery Company, Limited, Oldham, write: "Please forward us another 56lb. box of the 'Boron,' which we are able to state is of much greater benefit than any other preservative we have used, and you may refer anyone to us respecting the matter if desirable." Then there is a cider manufacturer whom I know who has got his name down on this list. That is all about sugar of boron. There is another preservative which is called by a fancy name, "Cynin." That I had analysed, and it proved to be a solution of salicylic acid and borax in glycerine. It certainly was a very good preservative, as far as keeping the sweetness went. I saw that tried on two small barrels of cider, about twelve gallons each; some was put soon after the cider was made into one barrel and none in the other, and both these barrels were left about anywhere, in the yard, or anywhere exposed, and afterwards in the winter time they were put under cover, and one spring, I think it was last spring twelve-months, they were broached in my presence. The one that had not the stuff in it was quite hard and had lost its sweetness, and also there was a little bitterness about it; while the other was just as sweet, I should say, as when it was made.

6582. (*Chairman.*) Was the hardness arising from the fermentation going too far?—Of course, from the sugar being all converted into alcohol. We call it hard, you call it dry; it is much the same thing. The other was perfectly sweet, as sweet as when it came from the mill I should think. It was quite bright, and you could not detect any taste whatever in it of any sort or kind. But I should say at once that that cider which had got hard and acid to a certain extent ought not to have been left about in that way. It was left about as an experiment, but otherwise it would have been tested from time to time, and if found to be getting too sharp or likely to get sharp, it would have been racked into another vessel, and so would have preserved a portion of its sweetness. At the same time, the cider that had been treated with cynin had not matured in the least, and it was just in the same condition almost as after it was first filtered. There was no maturing, and it was not, of course, nearly so wholesome as the hard cider, the dry cider would be. The next preservative that I have is Walter Gregory's powder. That I have not any testimonials about, but I had it analysed by a county analyst whom I know. He says: "It is almost entirely composed of salicylic acid, mixed with a small quantity of red oxide of iron. The oxide of iron is probably added in order to hide the white crystals of salicylic acid." The Committee, of course, are familiar with the effect of salicylic acid and borax. I do not know whether the Committee are aware that Mr. Lloyd, the Agricultural Chemist of the Bath and West of England Society, the year before last conducted some experiments upon the use of these preservatives, especially borax and salicylic acid, and that he found that in the ordinary—

6583. I am afraid we must get that from him if we get it at all?—That you can get from him if you are going to call him.

6584. I do not know that we are?—At any rate, you will find the information in the last volume of the Journal of the Bath and West of England Society, and I will not say anything more upon that. Then, to go on with my list; formalin, I believe, is not very much used by cider makers. I imagine that to be the case, because, as you will see in Mr. Lloyd's paper, it makes the cider cloudy, and it is difficult to get rid of the cloudiness; besides of course, it is a very horrible drug to put into anything. Then there is a preservative called "K. M. S.," which is a preservative or anti-ferment used by brewers.

I have not had any analysed. A specimen was to be sent to me, but it did not come. I suppose they found out to whom it was going. Then there is "Hawkes' Anti-Ferment"; that I had analysed. This is a different class of thing rather from the other preservatives. These anti-ferments, as they are called, or preservatives (they have got different names for them) are to make bad cider good. "Hawkes' Anti-Ferment" is mainly composed of calcium sulphite—this is the analyst's report—"with small quantities of lime. When calcium sulphite comes in contact with an acid sulphur dioxide is given off. The calcium will combine with the acid (say acetic acid), and form calcium acetate. The sulphur dioxide gas will destroy the ferments and will in time be changed into sulphuric acid, which will attack the calcium salts and form calcium sulphate or gypsum. I do not think"—this is the analyst's opinion—"Hawkes' cider restorer is capable of restoring a bad cider to its original good quality. It will (because it contains lime) reduce the acetic acid and cause the liquid to remain constant, that is, it will not ferment." I should say that I have here a pamphlet which might be useful to the Committee as regards formalin as applied to brewing and the manufacture of mineral waters, ginger beer, temperance drinks, British wines, pickles, jams, etc. I have read the pamphlet, and it seems that this stuff is very largely used, especially in temperance drinks.

6585. (*Dr. Tunncliffe.*) Is that pamphlet issued by the Formalin Company in connection with Schering's formalin?—Yes, and you can have it. It is called "A Treatise on the use of Schering's formalin as applied to brewing and the manufacture of mineral waters, etc." I got a friend of mine to apply for these things, and that was a pamphlet he had sent to him. Then with regard to Hawkes' Cider Restorer, here is a farmer who says: "It is with great pleasure I bear testimony to the excellence of your cider restorer, which I have purchased of you several years, for I have found it to restore cider when it was apparently worthless; one lot so bad that I could not tell what to do with it, but after using the restorer it was so much improved that I sold it for 25s. per hogshead"—that is about 54 gallons in that part of the world—"and many of those who purchased came again for more." Here is another: "The cider restorer I had of you last year I tried on some reamy cider"—that is, stuff that is ropy—"and it acted very well, and made very passable for farm cider which before could not use." The result of that is that cider which is beginning to decompose, and, in fact, is decomposed, by the use of this stuff is rendered palatable, and people are persuaded to drink stuff which is extremely unhealthy, which has already decomposed, and they do not know that it has been in this horrible condition or that it has got into this horrible condition. The flavour is altered, the taste is altered, and the nastiness is taken out of it, but the quality of the cider is entirely destroyed, and you cannot restore it.

6586. Can you, without letting us too far into trade secrets?—I do not know any trade secrets—

6587. Tell us how far cider is fortified?—No, I cannot. I should not think it was fortified very often—alcohol is too dear to buy to fortify cider with.

6588. What is too dear?—Pure alcohol is too dear. Nobody would do that. I do not think cider is very much fortified; there would not be so much harm in that, but I do not think it is often fortified.

6589. (*Dr. Bulstrode.*) Do you know if preservatives are used more in one part of the country than in another—whether their use is at all extending?—These testimonials that I have read are mostly from Somersetshire and Devonshire, but, I know nothing personally of their use in other parts.

6590. (*Chairman.*) Your own district being Herefordshire?—Yes.

6591. (*Dr. Bulstrode.*) Do you know whether preservatives are used in Normandy for cider?—I do not know much about Normandy cider—Brittany cider I have had.

6592. Are they used in that?—I do not know, and I could not tell you whether that is so or not. The French makers are taking very much more interest in the subject of cider-making than we are. Their books on the subject are very much more valuable than our books are—in fact, we have none, comparatively speaking, compared with theirs.

6593. Is it your position that preservatives in the case of cider are substitutes for the want of cleanliness?—Yes, especially the last class of anti-ferments that I men-

tioned. They induce people to be careless, and to a great extent there is carelessness in farming, the vessels are not clean, and the things get mouldy, and they do not take care with their fruit, and various other things. Then, afterwards, having made their cider in this careless way by the use of such an anti-ferment as that I last described, they can sell their cider at a fair price, which they could not otherwise do. That I think is a very bad thing. These restorers make palatable stuff in which decomposition has already commenced; the quality has gone before they are added, and cannot be restored, only the nastiness is neutralised and disguised—that is the way I put it.

6594. Do you think the public have any knowledge that preservatives are used in cider?—I should think everybody must now know that preservatives are used in almost everything, but I was going to say I hope they do not know of it in cider, because, perhaps, the trade will be injured.

6595. Do you know that certain cider firms advertise that their ciders are quite pure, and do not contain any chemicals?—Yes.

6596. You know that?—Yes, and I know that some of them add these things.

6597. Add these preservatives?—Yes, though they say they do not.

6598. You do not think the use of the term “no chemical used” is meant to imply “no preservatives used”?—No. I should certainly have an indication outside the bottles or vessels; they ought to be marked outside, “This has been treated with boracic acid,” or “This has been treated with salicylic acid,” or “This has been restored with so and so.”

6599. May I read you this of a certain cider—it is “guaranteed to consist only of the pure juice of Devonshire apples; no water, chemicals or saccharine are introduced; nor are these ciders artificially aerated”?—Of course, that ought to be good cider; that describes good cider.

6600. Without preservatives?—Of course it does. It says nothing as to any preservative.

6601. Without that may one take it that a statement such as this is meant to imply that no preservatives are there?—It is intended to imply that, and then if you had that cider analysed and found there were preservatives used in it you could have the seller up, of course, under the Food and Drugs Act.

6602. Do you think if preservatives are used in cider that the name and nature of the preservative used should be stated, and the amount of it used?—I do not think you could state the amount because it would be rather difficult to say the amount in a bottle, but you might say that preservatives had been used, or something to that effect; you might state the preservatives, or you might simply say that preservatives or a restorer, such as the last one I mentioned, had been used.

6603. Can you hand in to the Committee those testimonials and printed advertisements?—Yes (*handing in leaflets*).

6604. (*Dr. Tunnicliffe.*) Do you sterilise your pans or your vessels, I should say, by sulphur?—Yes, on occasions. I do not do it if they are perfectly clean; I do not think it is necessary.

6605. What test have you whether they are perfectly clean or not?—I have no test. I simply see if the vessel is scoured out well, and if the head has been taken out of the cask I look inside and see that it is perfectly clean,

or some of my men do, but I very often do it myself. I do not want to stop the fermentation entirely, and I am satisfied that fumigation has little effect in stopping fermentation.

6606. You see no objection, do you, to sterilising the vessels with sulphur?—No, I do it myself; I see no objection to it.

6607. Do you see any objection to the use of formalin or boracic acid?—I do not know enough about those drugs to be able to tell you their effect, but I should not use them myself, because from all I have read and heard of both, especially formalin, they are very deleterious drugs. Sulphur has been used for ages, and apparently has no effect whatever on the health, used in that way.

6608. What I wanted to ask you is whether your objections would apply to the use of preservatives for sterilising purposes, or whether they would apply only to the actual addition of the preservative to the substance when it is made?—I object to the use of these sterilising drugs, because they stop the fermentation, and therefore stop the maturing of the cider, and also because I believe them to be harmful. If you were to sterilise apple juice you would never get cider.

6609. I am speaking of the vessel now?—Speaking of the vessel, the reason why I sterilise, as you call it, or sulphurise rather, my vessels, is because I know that there are germs of all sorts about floating in the air, and you cannot wash every vessel out at the very moment when you are going to put fresh cider in it, and therefore to make sure there are no bad germs in the vessel I burn a sulphur match in it before I put the cider in, not so much to sterilise the ferment, not so much to prevent the liquor I put in from fermenting as to destroy any bad germs that may be in it. That is the main object that I have. Of course, you know that cider is sterilised. A great deal of the cider that is sold is sterilised by heat. It is heated up to about 150 degrees, but then after that you must carbonate it. Carbonic acid gas has to be forced into it in order to give it the fizz, which it would not otherwise have. That, of course, you know, but I do not like that process, because I think the sterilising destroys the quality of the cider, and also that the carbonic acid gas that is forced into it is not the same as the natural gas that is produced in the process of fermentation.

6610. (*Chairman.*) Did you say 150 degrees Fahrenheit?—Yes, about 150 degrees Fahrenheit. If it is subjected to the heat for some considerable time then 140 degrees would do, but if for a shorter time then it should be 160 degrees. The carbonic acid gas that is forced into it afterwards does not contain the ethers which originate in the course of the natural fermentation and the natural production of carbonic acid gas. You see to those ethers the quality and the taste of cider are mainly due.

6611. (*Dr. Bulstrode.*) Have you any reason to suppose that cider merchants who do not use preservatives in their cider, if the use of preservatives is not stopped, would eventually in self-protection, or as a matter of survival, have to use preservatives?—No.

6612. None?—I do not think so at all.

6613. Have you any reason to suppose that the non-use of preservatives would be detrimental to those who use them now?—Of course it would be; it would stop a good many people turning bad cider into palatable stuff, which is what we want to do; but it would not affect the honest trader, and it would be a great deal of benefit to him.

*Mr. C. W.  
Radcliffe-  
Cooke, M.P.*

9 Feb. 1900.

## TWENTY-THIRD DAY.

*Wednesday, 2nd May, 1900.*

PRESENT :

The Right Hon. Sir HERBERT MAXWELL, Bart., M.P., F.R.S. (*Chairman*).

Professor T. E. THORPE, F.R.S.

I. TIMBRELL BULSTRODE, Esq., M.D.

CHARLES J. HUDDART, Esq., *Secretary*

*Mr. A. S.  
Lough.*

Mr. ARTHUR S. LOUGH, called; and Examined.

2 May 1900.

6614. (*Chairman*.) You are a member of the Irish Agricultural Organisation Society?—Yes.

6615. And you are connected with numerous other dairy societies?—Yes.

6616. You are Managing Director of the Cavan Creameries, Ltd.?—Yes.

6617. You also own a private creamery?—Yes.

6618. I believe there has been great activity in setting up the creamery industry in Ireland of late years?—Yes, a most extraordinary revolution has been accomplished there.

6619. Can you give us an outline of the facts?—Yes. In the south of Ireland the industry commenced about eight or ten years ago and in the north of Ireland about two-and-a-half years ago, and in that time we have established between 500 and 600 creameries in Ireland. Of that number the co-operative creameries which I have been principally interested in as a member of the Organisation Society have established about 260 co-operative creameries in the country. In Ulster the revolution has been more extraordinary than in any other part of the country. Ulster was not very much noted as a dairy district some time ago, but now, in the last three years, we have got in Ulster 108 co-operative creameries working and thirty in course of formation. The fourth co-operative creamery established in Ulster was the Killesandra Creamery, which I was president of and which I started, and that creamery had a turnover of £3,500 in its first year, 1897. In the following year the turnover was £9,000, and in 1899 it was £17,500; and this year we estimate the turnover will be £25,000.

6620. That constitutes a pretty general revolution in the Irish dairy system, does it not?—An extraordinary revolution.

6621. To what extent do these creameries as a rule rely upon the use of preservatives?—Nearly all the creameries at present use preservatives in summer. Some do not use them, but the majority use preservatives.

6622. Do these co-operative creameries manufacture butter?—Yes, only butter. We make no cheese and we sell very little cream. It is all fresh butter. It is called fresh, but, of course, it is a week or so before it is used by the consumers.

6623. What do you do with the separated milk?—It goes back to the farmer. The separation takes place immediately the farmer comes to the creamery with his cart of milk, and it goes back to the farmer the moment it is separated. He waits for it.

6624. What does he do with it?—He feeds his calves. The calves in the north of Ireland and round the district which I know most about are a great source of profit, and the milk must be very carefully separated and handled.

6625. You have not found it impossible to handle your butter without preservatives, have you?—Certainly. One of the reasons that we use preservatives is because we have been asked to use them by the wholesale firms. As a matter of fact, a far less quantity of preservative might be used than is used. It has been treated practically as a salt. I think I can speak for the Organisation Society, for it gets the reports daily and weekly of these creameries, and, to my knowledge, we have never had any complaints regarding the use of the preservative in butter—never

the slightest. As a matter of fact we will do without preservatives in the creameries in which I am managing, and simply because we think we will get a little higher price. That is our intention.

6626. That is to say, that you could make the butter and get it off your hands without any preservatives, but the wholesale dealers require to keep it longer than it would keep sound without a preservative. Is that it?—That is it exactly. We find that there is not a demand for it without. I suppose the wholesale dealers find there is not a demand for a huge quantity of what might be described as saltless or fresh butter, and, consequently, they want the butter to stand a certain time, and we make the butter to suit them. On the other hand, if the development goes on with regard to fresh butter that has commenced it is very probable that preservatives would naturally be used less. We try to get butter into consumption quicker from Ireland, and we are able to do this now by the revolution in the creameries that has taken place. We get a better price for the butter that is put in the market and used fresh.

6627. Witnesses from Ireland have complained very bitterly of the delays in the traffic from imperfections in the railway and steamboat service?—Excuse me for one moment. I should like to say that there is a distinction that should be drawn between the north and south of Ireland with regard to this system of preservatives and pasteurising. In the south the system is that the cows should be arranged, as far as possible, to calve, from March, say, to the 1st of May, but in the north of Ireland we are not so particular about this, because we winter-feed more in the north. So that in the south the necessity for pasteurising perhaps is not so keen as in the north, for this reason—that the cows calve so far as we can determine it more regularly. They are arranged to calve between March and May in the south, so that the farmers shall not have winter feeding—that is to say, they will not have winter milk to the same extent that we have in the north. Now, in the north we do a great deal of winter feeding, and if you feed in houses you cannot get as good a flavour in the butter unless you pasteurise. It is not easy to get it. It is just the same as in Sweden and Denmark, where it is practically essential and necessary, that they should pasteurise, because they have their cows house-fed for eight or nine months. It is not natural to assume that those cows, no matter how carefully fed in the house, would produce butter as good as butter from grass-fed cows, and of necessity to get the best butter where cattle are so long in the house you ought to pasteurise. Now, we have come to the north of Ireland, where we feed cows in the winter and produce a good deal of butter in the winter. In the north they work all the winter, but in the south of Ireland a great number of the creameries shut down during the winter, therefore we are intermediate between Denmark and the south of Ireland. They must pasteurise to produce good butter, but we come in and say we will do both.

6628. Who must pasteurise?—The Danes must to produce the best butter, because the cattle are so long house fed.

6629. On what is that statement founded?—For instance, I keep a lot of cows myself, and I make winter butter. If you do not turn out your butter very promptly and get it into consumption in a couple of

days, or if you happen to use mangels or turnips, you can hardly avoid a house-fed flavour in your butter, and pasteurising will remove that to a great extent. Now take the other position which is that I have my cows out in grass in summer, and in which they are milked in the field, as they are in many places in the south of Ireland. The milk can is in the field, and the cart takes the can from the field to the creamery each morning and evening. Now, that butter should require no preservative, or pasteurising, but it should be the best butter for prompt consumption.

6630. Are you dealing with pasteurisation solely as a means of purifying the flavour of the butter?—As keeping it pure, so to speak. We all know that if cows are milked in a house, and if the can of milk is carried from that cowhouse to the dairy, the time of passage through the house and the time it remains in the house, especially in the cowhouse where the milking takes place, is the time that most of these organisms are developed and where they most rapidly develop.

6631. Would you be surprised to hear that some witnesses from the south of Ireland have alleged pasteurisation in Denmark as a reason for the inferiority of the Danish butter flavour?—I would not say so.

6632. You do not agree with that?—No, not at all. I believe pasteurisation is most valuable, and I do not agree with that statement.

6633. To what temperature do you raise it in pasteurisation?—175 degrees to 185 degrees Fahrenheit. That is about the temperature used. We are putting up ice-making plant and cold storage plant, and of course that makes it much easier to do it in case we wish to stop using preservatives—in case it was necessary or that the result of this Committee was that they should have to be done away with.

6634. Are you aware that there are other methods employed of improving the flavour of milk and cream from house-fed cattle?—Besides pasteurising it?

6635. Yes?—No, I am not aware of it.

6636. You have not heard that the introduction of certain ferments or cultures is employed?—With regard to that, if you pasteurise cream you must use a pure culture to ripen it to make butter, but I never heard of any way of improving the milk of house-fed cattle by that means. It is to ripen the cream after it has been pasteurised that we use the cultures.

6637. I interrupted you just now, I think, to ask you about the complaints we have had from the south of Ireland as to difficulties of transit by rail and sea. Have you experience of that in the north of Ireland?—Indeed we have. It is the greatest curse practically that we have got to deal with in Ireland. For instance, we get no suitable wagons for our butter. The wagons that the butter is put into may be cattle wagons or wagons that have got any sort of goods to carry for local stations. There is no such thing on an Irish railway as a refrigerator car at the present moment, I believe. I know this as a fact that has come under my own observation that a large quantity of butter was being sent from the Killeshandra Creamery in August. The wagon that it was put into was just pulled in out of the sun. It was not even standing in a shed. The butter was put into it and it was not a clean wagon. That butter came across to London, and a couple of days afterwards we heard that it was very bad and very inferior. Butter sent the same day to Belfast was quite good and quite sound, so that it must have been owing to the difference between the two methods that the butter was damaged in transit.

6638. Have representations been made to the various companies on the subject?—Yes, we have made representations, and probably we will get some assistance presently, because we have got a new Agricultural Board there, and it will be able to bring pressure on the railways I hope.

6639. You have already explained that the development of the trade has been very rapid?—Yes, with regard to creameries it has been so, but there has been always a lot of butter of the old style bought in the local markets. We are now concentrating the thing more so that it would be easier to deal with it. Then there is another matter. For instance, if we send our butter by the ordinary goods train it is a very slow business to get it into London or Manchester from the centre of Ireland. There is no comparison between that and the speed with which Normandy butter is got into the English markets. For instance, butter put on rail on goods trains at Killeshandra, Cavan, or Clonas should be in

London within two days, that is, butter put on rail say on Wednesday evening should turn up on Friday morning in London. Now, that is a very simple statement, but on the Midland Great Western Railway of Ireland if there is any big fair on within any reasonable distance, everything is put aside—traffic is dislocated and butter delayed. These railway commissioners that you have in England are the theoretical body that we should have to influence the railway companies, but I do not think, as far as my knowledge goes, that we have had a single case where they have ever given the slightest assistance to us.

6640. Are there any traders' wagons in the butter trade?—No, none in the north of Ireland, and I know of none in Ireland.

6641. You think they would be able to help?—Certainly they will be a help. Another thing is most extraordinary, that is that there is some new Act of Parliament or some re-arrangement by which you cannot proceed for compensation against the railway companies in an easy way. Supposing we are sending butter to Brighton from Ireland, it would probably pass through the hands of four different companies. If the butter was damaged by the third company that got it we would have to proceed against the first company. They would prove the delivery to the second company. The second company would prove delivery to the third company, and then we should have to pick out which of the four companies had damaged the butter and proceed against that company. Anything more idiotic for business firms to have to deal with than that you can hardly imagine. It is a most extraordinary position. We had a case like that at Killeshandra. We got the receipt from the Midland Railway Company and proceeded against them. They proved delivery to the Northwall Boat. Then we had to proceed against the London and North-Western Company—a most troublesome business—and the company that has received the butter is not bound to say who has damaged the butter. That is a most unsatisfactory position. We were defeated and appealed the case, and it was contested, and we were beaten.

6642. What is your experience as to factory butter?—I never had anything to do with it. We do not touch that at all in the creameries.

6643. Are there any butter factories in the north of Ireland?—There are, and they are a great source of difficulty with regard to the butter business, because there are factories at the present time in the north of Ireland which buy up butter in the local markets and bring it to some town where they have got what they call a blending establishment. That butter is blended there, and after it is blended it is packed identical with our creamery packages, and no brand is put on it at the town where it is blended, but a brand appears on that butter in the English market, and as a matter of fact it is very often sold as creamery butter.

6644. Is there any reason why it should not be sold as creamery butter?—It is not creamery butter, it is butter bought in the local market.

6645. Has creamery a definition?—Yes. This practice is misleading. For instance, we brand all our butter—at least the co-operative creameries do that do their business right—"Guaranteed pure centrifugal creamery butter," and they could, as you indicate, put that same brand on and not come within the law—you could not take proceedings probably against them, because it is made from cream, and they use a table that is centrifugal in its action, but it is very different butter.

6646. Do you look upon factory butter as inferior to creamery butter?—There is not the slightest doubt about it. Everybody knows that—I mean everybody in Ireland, in these districts, knows it well.

6647. Is not one of your most formidable rivals the Normandy factory butter?—That is a very different thing. I am very glad you asked me that question, because there is a great misapprehension in most people's minds with regard to that. Factory, or milled butter as we call it in Ireland, is the butter bought from the farmers in the local markets who still make the butter in the old way. For that butter the average price in the local markets is 2½d. per pound, or 25s. 4d. a hundredweight less than creamery butter in the same locality. It is salted butter that has been kept in the house for a long time and could never be classed as fresh butter under any circumstances—quite the reverse. That butter is brought to a blending establishment, and they make it a more even thing in quality, and may improve it

Mr. A. S.  
Lough.  
2 May 1900.

Mr. A. S.  
Lough.  
May 1900.

in other ways, and it is sold then as creamery butter. In the Normandy system the farmers churn their butter, and as far as I understand it they do not put salt in it even, and it is immediately collected and brought to the blending establishment. That is a butter made on an entirely different system from the milled butter, which means butter which has not been immediately churned, and it is also butter that has been churned under the most unfavourable circumstances, because it is done under the old system at little farm-houses with no proper dairy for doing it. It is quite a common thing in Ireland for cream to be collected in the dwelling rooms of the cottages, and there is no more shocking system than that—it is most dangerous. That butter is called milled or factory butter in Ireland. There are a few factories in Ireland where the Normandy system prevails.

6648. What do you say about colouring matter in your creameries?—That is hardly used at all.

6649. Is the winter butter the same colour as the summer butter?—Very nearly. There are some dairies that use annatto. They use it in very small quantities. The dairies that I know most about in the north of Ireland I think hardly use any.

6650. But your winter butter will naturally not be the same colour?—It is astonishing how little difference there is. I was in the Killeshandra Dairy; it was in the month of March, and they were making butter, and I went to speak to the dairymaid and said: Do you use any colouring matter; and she said No. You would not want butter of any better quality or colour.

6651. What cows are they?—They are of mixed breed—crossed, Shorthorns, and others.

6652. No Channel Island cows amongst them?—None. Annatto might be used. They keep annatto in most dairies. A very little mistake in the scalding may cause them to want it. It is, of course, not as deep in colour as the summer butter, but it is of very good colour.

6653. You do not find the wholesale dealers like a uniform colour summer and winter, do you?—Really I do not think there is a great deal of difficulty as to the colour. In some places in England and Scotland they want it deeper in colour than others.

6654. Are you acquainted with Denmark—have you been in Denmark?—No.

6655. But you are acquainted with the system, are you not?—Yes, I have met a lot of Danes and experts from Denmark.

6656. The cows are kept in the house eight or nine months a year, are they not?—Yes. I have a Dane working for me at the present time, and he says that the time would be eight or nine months.

6657. Would you say that the Irish enjoy a great advantage over the Danes in that respect?—Certainly. Our cows, I should say, are in the house from four to six months.

6658. Therefore, if your trade were well established, and thoroughly well organised, may we assume that the restrictions which are placed on the Danish producer in regard to the use of preservatives would not be too onerous for the Irish producer?—Certainly not on the conditions you state. It will take some time just to get it organised.

6659. (Professor Thorpe.) I gather that the tendency of your evidence is to deprecate the use of preservatives in agricultural products?—Quite so.

6660. Do you think, by due attention to cleanliness, and, if necessary, by the use of pasteurisation, the use of preservatives could be entirely obviated?—In a short time—in a few years with proper organisation, as the chairman has stated. That is in the creameries of the country.

6661. But assuming that the system, however, was organised, and assuming that the organisation you have spoken of, the Irish Agricultural Organisation Society, had come sway, do you think it would be no hardship to the whole of the Irish butter producers, whether they be factory or whether they be creamery, to do away with the use of preservatives?—Personally I would be in favour of doing away with it, but as to it being a hardship it would take a considerable time before it would not be a hardship. There are some districts in which it is very hard to get creameries established, and it would be unfavourable there.

6662. In the meantime, before that happy time comes, perhaps it would be an advisable thing or an expedient thing to require the butter producers to declare the presence of preservatives in their butter?—On that subject it seems to me theoretically a very nice thing to say, and it is the first thing that would occur to me to say, but, on the other hand, it would be, I think, better if it were left like other food products so that you should limit say the quantity of preservative used, and that the different analysts should undertake to declare whether it is injurious or not or something like that. It would handicap the trade a good deal, I am afraid, if you did just say plainly that you must declare whatever preservative you use.

6663. How does it handicap the trade?—For instance, supposing a man discovered a harmless preservative and that he used it, it being absolutely harmless, would it not be rather hard on him if he had to say what it was?

6664. But are not you rather begging the question when you assume that the preservative can be harmless?—I would rather hear men better up in the exact subject—chemists and others—say about that. If it is declared harmful, I, for one, should say it should not be used. That is just the point.

6665. Of course, the term harmful is a question of degree. How do these preservatives do their work as preservatives do you imagine?—As a preservative I should say that they stopped corruption, so to speak. You might put it in that way, although it is a rather coarse way of putting it. They hold back decay.

6666. But is it not the fact that they work by virtue of their action upon the organisms which induce these changes that you call corruption and decay?—Yes, very probably.

6667. Then are not those or similar organisms at any rate concerned in every digestive process?—I should say they are, but it is hard to say that a thing that has been used so long, and that you hear no complaints of in any shape or form, is harmful. We use poisons every day, and without the poison some food would be of little value.

6668. Confining our attention for the moment to butter, surely any process that arrests the action of digestion must be to some extent, at all events, a harmful process?—Being an unprofessional man I should be inclined to agree with you.

6669. Then if you can do without, as you seem to say you evidently can do without, the use of preservatives, and if you are inclined to admit that the action of preservatives is to limit the process of digestion, surely the consumer is entitled to know whether or not he is eating something which has been more or less dosed with an antiseptic?—I know, if I were the man eating it, I should like to know that.

6670. You would like to have that made plain?—Yes. Personally I have no objection, and I think it is quite right.

6671. You think it is quite right, then, that the use of preservatives should be declared?—It is quite right that it should be known that preservatives have been used.

6672. But how is that to be known to the consumer unless it is declared on the article that he is buying?—You did not quite catch my point. For instance, there are preservatives that everything you have said would apply to, but I think there are preservatives that what you have said might not apply to.

6673. Let us confine ourselves to the preservative which is actually used, which is a mixture of borax and boracic acid. The action of borax and boracic acid is to retard the process of digestion to a certain extent?—From the evidence given before the Committee I think that is so.

6674. Therefore if the mixture of borax and boracic acid has that influence upon the digestion, surely the consumer has the right to know whether his food is being dosed with that substance?—Yes, but is not that being done by the analyst?

6675. But the analyst expresses no opinion about that—it is not his business. His business as an analyst is to find out whether these things are or are not there. Now, if it is the fact that borax or boracic acid has this effect, surely the consumer has a right to know he is being dosed with that substance, has he not?—Yes, certainly, but I do not think I would make an exception as regards butter compared with other foods.

6676. Your meaning is on the question of butter?—I am in favour of having pure butter without any

preservatives, good, bad, or indifferent, and the creameries in which I am interested, and which I have assisted to establish—and they are a good many—are preparing to do without them absolutely.

6677. (*Dr. Bulstrode.*) In describing the methods which are adopted by the co-operative creameries in Ireland, you do not mention the regulations with regard to cleanliness and with regard to washing the milker's hands and the udders of the cows and so forth, prior to the milking, but is that insisted upon by the creameries now?—Yes. As far as we can possibly do it we are most strict and most anxious to carry out that very idea. We issue to every milk supplier a very carefully prepared leaflet, just dealing with the facts as you have stated them, and saying that the udder of the cow should be washed with a flannel cloth, and that the hands of the milker should be washed before commencing milking, and also other things, namely, to take the milk out of the cowhouse when one cow has been milked and not to leave it standing till the others have been milked—keep your milk in the open air as much as possible, and do not bring it into the house. We also put all our milk into cans that are watertight with the lids on, and we ask them to leave them out under a tree instead of in the houses.

6678. What steps do you take to ascertain the purity of the water supply to each of the farms?—We never do anything as regards that, I am sorry to say.

6679. Nothing so far is done?—Nothing so far is done, but in the north of Ireland the water supply is good—there are so many running streams and pools. Unfortunately we get a little too much of it in a way.

6680. Is straining insisted upon at the farms?—Yes.

6681. Could you tell the Committee the nature of the preservatives chiefly used?—Borax chiefly.

6682. You say, "I have no doubt but that butter made from unpasteurised cream and treated with preservative will keep longer than butter not so treated." Is that a general statement, or have you any experiments to speak from?—Personally, I have made no experiments, but I know a large number of men, the managers of creameries, who have made experiments,

and that is the conclusion we have arrived at. I have had experiments carried out.

6683. You think that if preservatives were prohibited at the present moment it might dislocate the trade for a time?—It would give a great deal of trouble.

6684. But you would not think that was an argument for the use of preservatives provided the Committee came to the conclusion upon scientific evidence that their use is harmful. You would say that the trade must adapt itself to it?—It would be a great labour in many parts of Ireland to do it, but I suppose it must be done.

6685. You say that if such precautions as you advise and illustrate were taken that the use of salt might be dispensed with?—Yes, if the butter came into immediate consumption, certainly; but you must have it more or less if you want to keep the butter for any lengthened period.

6686. As regards the Irish trade, do you think it possible to dispense with the use of salt?—No, I am afraid not. Cold storage is not developed enough, and transit arrangements are too bad.

6687. They are infinitely worse than they are in Denmark, I suppose?—I should certainly say so. The Government give a lot of assistance in Denmark. We have got none in Ireland.

6688. Do you know anything as regards the cream trade?—A little. We do something in the cream trade.

6689. Is it your opinion that the cream trade can be carried out without the use of preservatives?—I should not like to give an opinion upon that subject. I am not sufficiently well up in it. We have sold cream without any preservatives used in it, but it wants to go into consumption very promptly.

6690. You have no objections, as a practical man, against the use of pasteurisation?—Certainly not, except the trouble in establishing it, and the necessity for dealing with large quantities of milk, and that is a very great practical difficulty, but we are overcoming it.

*Mr. A. S. Lough.*

2 May 1900.

## TWENTY-FOURTH DAY.

*Monday, 7th May, 1900.*

PRESENT :

Professor T. E. THORPE, F.R.S., in the Chair.

H. TIMBRELL BULSTRODE, Esq., M.D.

CHARLES J. HUDDART, Esq., *Secretary.*

Dr. ROBERT HUTCHISON, called; and Examined.

*Dr. R. Hutchison.*

7 May 1900

6691. (*Dr. Bulstrode.*) I think you are connected with the London Hospital?—I am assistant physician at the London Hospital.

6692. Have you been deputed by the London Hospital to give evidence before this Committee?—No, not so far as I am aware; I was deputed by Great Ormond Street, with Dr. Still, to give evidence.

6693. You have, I think, certain experiments to put before the Committee. Will you kindly put them in your own way, in the first instance?—I do not know that I am prepared to say much about the effects of preservatives on children. The only preservatives that I have tried on myself are boric acid and borax. I made some experiments on the effect of boric acid on the acidity of the urine; I happened to be making such experiments when I got a notice asking me to give evidence here, and then I extended these experiments with a view of seeing what would happen if one took the drug more continuously. The net result was pretty well this—that even such a dose as ten grains of boric acid, taken twice a day on a full stomach by myself for a length of time up to a fortnight continuously, had practically no effect at all. I observed no bad effects.

3017.

6694. No bad effects. In what way?—There was no sort of stomach irritation or intestinal irritation or discomfort, or anything of that sort at all.

6695. As far as you are aware, you are quite a healthy individual, and you have no departure from the normal in any way which would modify the effects?—None at all. I think I may regard myself as perfectly healthy. If I have a weak point at all it is my stomach. My stomach is perhaps more irritable than the average; so if it produced any effect one would have expected it to produce vomiting in myself as much as in the average man, anyhow.

6696. This went on for a fortnight?—Yes.

6697. You observed no bad effect whatever on yourself?—None at all.

6698. Have you made any other experiments with regard to the administration of borax?—I took small doses of borax and boric acid solution—five grains—which I believe is a frequent preservative used.

6699. Yes, it is?—That continued for the same length of time had also no effect.

G G

Dr. R.  
Hutchinson.

7 May 1900.

6700. Was it five grains of the mixture?—Five grains in the mixture— $2\frac{1}{2}$  grains of each. That was taken twice a day, so ten grains of the mixture were taken.

6701. What do you infer from your own personal experiments in the matter?—I should have inferred that the amount of boric acid or borax which would be sufficient to preserve the quality of milk that an adult would be likely to take in the course of twenty-four hours could not, in the average healthy man, produce any signs of bad effects.

6702. You know that there are certain cases on record in which the continued use of borax or boric acid has apparently produced harmful results?—Yes, I have read of such cases.

6703. Have you prescribed those drugs in your own practice much?—I have prescribed borax for epilepsy sometimes in adults, but not very frequently. It was in hospital out-patient practice; there it is difficult to keep an eye on one's cases. I never noticed any bad effects for the comparatively short time that one was able to be certain of having the people under proper observation.

6704. Did you notice any good effect?—I gave it combined with bromide, and it was difficult to be sure to what extent the good effect was due to the bromide and to what extent it was due to the borax. In those cases of epilepsy unquestionably one saw a great diminution of the fits; but, of course, the bromide alone might have had a great deal to do with that. Still, I had the impression that one got a greater effect than if one had given the same dose of bromide without the borax.

6705. We have had it in evidence before us by several witnesses that the administration of boric acid or borax is contra-indicated in certain conditions, particularly diseased conditions of the kidneys. Have you got any information which would tend to support or to contra-indicate that conclusion?—I am afraid I have not, and I do not think I should like to express an opinion about that.

6706. Boric acid is excreted by the kidneys, is it not?—Yes, it is excreted by the kidneys.

6707. And if the kidneys were diseased you would suspect possibly that some bad effect might accrue?—Conceivably, it might in an acutely inflamed kidney; I think it might be expected perhaps to increase the congestion a little; but, on the other hand, it is so much diluted by the urine by that time, that I should think the effect would be very small.

6708. Do you know the experience of Dr. Bond, of Westminster Hospital? He gave evidence before us chiefly as to the harmlessness of boric acid, but in certain cases he told us he had had bad results, and in those cases the kidneys were diseased, and he had to stop it. Have you any information of that kind?—No, I have no information on that particular subject.

6709. It is also stated by Sir Thomas Lauder Brunton that the administration of borax is attended with danger in pregnancy; have you any evidence in support of that statement?—I did not know that it had any specific effect any more than anything else that is apt to produce irritation of the intestine.

6710. He says: "It has been supposed to have a special action upon the uterus, and has been employed in amenorrhœa, dysmenorrhœa, and puerperal fever and convulsions. On account of its asserted power to increase the uterine contraction it ought either to be avoided or employed with care during pregnancy."—I have no personal information on that, as far as I know it is not often used.

6711. You have no information on that point?—None at all.

6712. Have you any more evidence as regards your own experiments with reference to boric acid or borax?—No, I am afraid I have nothing else that would be of any value.

6713. We have been told before this Committee that as much as 80 grains of boric acid have been discovered in a pint of milk. Would you as a physician see in that any danger?—Yes. I should not like to take 80 grains of boric acid in a dose.

6714. Of course, this is in milk?—Even diluted with a whole pint of milk I should not care to swallow so much at once.

6715. Do you see any danger in giving a child three pints of milk with we will say 10 grains of boric acid in it per pint?—That is 30 grains in a day?

6716. Yes?—I could easily understand that it might be dangerous in the case of children, whose intestine is more irritable than that of an adult.

6717. Do you think it is possible that the use of preservatives generally in milk might tend to veil the effects of partial decomposition?—No, I cannot see why they should. I mean the only way in which one can judge the decomposition of milk surely is by its becoming sour.

6718. You do not think the addition of preservatives would tend to veil decomposition at all?—I cannot think so.

6719. Do you think that the use of preservatives is in the interests of the public health or not?—I should say yes, because I think the amount of disease produced, especially in children, by allowing milk to go at all bad is probably greater than the amount of disease produced by the use of the preservatives.

6720. That would rather apply, would it not, if the preservatives were applied directly the milk were drawn from the cow?—It would more strongly then, but even if the preservatives be added to the milk later, I think that probably it would do less harm than the milk having become at all turned would do, because then it is very apt to excite diarrhoea in children.

6721. You would rather have preserved milk than decomposed milk?—Certainly.

6722. Would you advocate the continuation of the state of affairs which obtains at present, that is to say, that the use of those things is one may say absolutely unrestricted, as as much as 80 grains of boric acid have been found in a pint of milk?—Of course, that is a state of things which one would like to render impossible, because 80 grains is a quite unnecessary amount for the mere preservation of milk.

6723. Would you suggest that a maximum should be fixed for each of those preservatives?—Yes, I think that that probably would be the best practical way out of it. No doubt the ideal thing would be for milk to be carefully preserved—sterilised or pasteurised—immediately after it was drawn without the addition of any chemical preservative; but that, I suppose, is unfeasible.

6724. Would you as having a great experience of the Children's Hospital, see any objection to the use of sterilised milk for children?—No, I think its advantages enormously outweigh any disadvantages which have been attributed to it.

6725. Quite sterilised milk, I am talking of?—Yes.

6726. Do you think the difficulty would be met by pasteurisation?—I think pasteurisation would do a great deal of good; it would kill most of the disease organisms, and would preserve the milk from going sour for at least a considerable number of hours.

6727. Amongst hospital physicians do you think this question of the use of preservatives in food is regarded as a serious one from the point of view of the profession?—No, I think there is very little attention paid to it. But then of course in hospitals we get probably the better supplies of milk; we get our milk from the better dairy companies, and they know, I suppose, that they are expected to supply us with a fairly pure article.

6728. Do you think that this question of preservatives is a matter of at all serious concern to the hospitals?—I should say not at all; I should say in out-patient practice at the Children's Hospital, and my colleague, Dr. Still, will agree with me, the question of the probability of food preservative being the cause of intestinal irritation almost never comes into one's head.

6729. Have you never looked at it in the light of the presence of the preservatives somewhat stultifying the physician's practice?—I do not think so, because one finds that by modifying the milk in some other way, the mother still continuing to get it from the same source, you are able to make all the symptoms usually disappear without considering the question of changing the supply of milk.

6730. Suppose, for instance, when a physician goes round the wards, he prescribes, we will say, 5 grains or 10 grains of boric acid, would not his practice be rather stultified if it turned out that in the milk there might already be 20 grains of boric acid?—Yes, of course, it would in that sense.

6731. With regard to the use of salicylic acid, would it not be rather a serious matter if a physician in deciding

Dr. R.  
Hutchison.

7 May 1900.

whether he should prescribe 15 or 20 grains found that already the patient was taking perhaps 10 grains a day in addition?—Yes, unquestionably it would.

6732. Does it not rather affect the medical profession in that sense?—It does, of course, in that sense.

6733. Not only in the hospital perhaps, but also in practice outside?—Yes, even more I should think outside. But then, of course, that is only where you are using those same things as drugs which are also used as preservatives; I mean if you are ordering salicylates for a patient it would not much matter whether there was a moderate amount of borax or boric acid in the milk.

6734. But it would matter if you gave him the same drug?—Yes, it would matter because then you would get double the effect.

6735. In other words, would you say as a medical man that the indiscriminate use of drugs for food preservatives is or is not a serious matter for the medical profession?—That is just one of those questions to which it is difficult to give one reply. It depends entirely on the amount in which they are used. I should say that if the amount was strictly limited it would not be a serious matter.

6736. I said the unlimited use; the uncontrolled use I intended to say?—Certainly—there can be only one reply to that. The uncontrolled use would be a bad thing from the point of view of medical men.

6737. With regard to salicylic acid, could you tell the Committee as to whether there are any conditions which contra-indicate its use as a drug?—It is a depressing drug. I have seen it produce great cardiac depression, and one has to use it, I think, with some care in conditions in which there is great feebleness of heart. That is, I think, the only condition that presents itself to my mind where one would be careful of its use.

6738. Would you use it in diseased conditions of the kidney?—One so rarely is known to prescribe it there. If you had a man with acute rheumatism and at the same time an acute nephritis, which is a very rare combination, one might have to consider seriously the question whether the salicylic acid would not injure from the point of view of the nephritis. That is a question which, as I say, in practice hardly ever presents itself to one.

6739. Take the case of a number of people who are not coming under medical treatment whose kidneys may be diseased before they come under treatment; do you see any danger to the public health in their taking considerable quantities of salicylic acid unknown to them?—I should think the danger was very small, because those forms of kidney disease which are not under treatment would be very chronic forms, in which I should think salicylic acid would be the least likely to do harm; I should think it was in the acute forms of kidney disease it was most dangerous.

6740. Do you know anything as to the use of formalin?—Nothing at all, except I am told it is pretty largely used now.

6741. Do you know anything as to the effect of formalin?—No; I have never had occasion to administer it by the mouth; of course, it is an exceedingly irritating substance locally, and one might expect it to have bad effects.

6742. From what you know of the effects of formalin, would you advocate its use as a preservative?—That depends entirely. The amount of formalin required to preserve milk, for instance, may be so small as to be quite harmless locally. That I cannot tell, never having tried it.

6743. Can you tell the Committee anything with regard to benzoic acid; would you see any objection to its use as a preservative?—I have found it very irritating myself when swallowed.

6744. In what doses?—Five to ten grains—I have never taken more than ten. I took some when I was making those experiments on the acidity of the urine, and I found it exceedingly irritating to the stomach, but it never produced vomiting.

6745. On a full stomach, was this?—That was on an empty stomach.

6746. Five to ten grains, three times a day?—No, I took it in single doses always.

6747. Have you any experience of the harmful results on other persons to whom you have prescribed it?—No; it is frequently prescribed for septic conditions of the urine.

3017.

6748. Have you prescribed it much?—It is more prescribed by surgeons than physicians in those cases. I have frequently enough prescribed it, but I do not recollect ever to have seen local irritation of the stomach produced by it.

6749. Might we ask you to sum up your position with regard to preservatives both in relation to public health, and in relation to the profession?—I should say that their uncontrolled use is, of course, a thing to be deprecated, but that used in the quantities which are just required to prevent putrefaction, should think that they do very little harm, if any, and that the harm would probably be confined to some especially susceptible individuals, who are probably not numerous.

6750. Who are idiosyncratic, would you say?—Yes; and that the harm likely to result from food going at all bad from want of preservatives would probably be greater than the harm that would result occasionally from the use of preservatives in the quantity which is necessary to preserve food.

6751. (Professor Thorpe.) When you say food, do you mean milk alone or do you mean food in general?—I was thinking more of milk at this moment.

6752. It is important to be rather precise?—I should think that it could be extended probably to apply to all foods if it holds good of milk.

6753. (Dr. Bulstrode.) Do you think there is any objection to bringing a preservative, which undoubtedly either kills or checks the activity of certain micro-organisms, into contact with the gastric cells?—It depends entirely on the degree of concentration with which it is brought into contact with the gastric cells.

6754. You would say that 80 grains of boric acid in a pint of milk would be likely to affect prejudicially the gastric cells?—I should not like to give any opinion about that. I would feel uncomfortable if I were administering it, and I should not like to administer it, but I should not be surprised to hear that it produced surprisingly little results.

6755. Are you familiar with the experiments which have been made in connection with borax, with boracic acid, and with formalin?—I have read a summary of Leibreich's experiments.

6756. What do you regard those as tending to show?—As far as they went they showed that the local effect was surprisingly little, but his experiments were made purely on the lower animals. Rabbits, guinea pigs, and dogs, if I remember rightly.

6757. And adult dogs chiefly?—Yes. He has published a small book on the subject, I believe, but I have not read the original; I have only seen a summary of his results, and they went to show that he did not in any case find irritation of the stomach or intestine.

6758. Do you think that one can infer what may happen to quite sucking puppies from what may happen to adult dogs?—No, I think one has got to be very careful in making such an inference.

6759. (Professor Thorpe.) Do I gather that you see any particular disadvantage in the use of preservatives in milk?—That is not my position. It depends, as I said before, entirely on the amount of them used. I think that the use of a quantity of boracic acid or borax, or of a mixture of them just sufficient to preserve the milk, would probably be harmless in the immense majority of cases in any quantity in which milk is likely to be taken in the day up to four or five pints.

6760. If, however, it is pointed out to you that practically a well organised milk supply can be maintained all the year round without the use of such preservatives, and if it is further pointed out to you that the use of such preservatives tends to prevent the proper appliances being used in dairies, and to prevent the proper economical production of milk being brought about, would that modify your position?—Granted that it is possible to maintain the supply that you speak of—a perfectly pure supply—I think one would admit at once that that is the ideal to be aimed at.

6761. We have had it in evidence that a very large amount of the milk supplied to the best organised companies in this city is supplied all the year round, and is brought from very distant places, without the use of any preservative whatever?—Yes, but supposing the milk goes into the homes of the poor, and is kept standing for some time in a dirty room in hot weather, I should think it is exceedingly likely that, although it was perfectly pure when it was supplied, it would be beginning to go bad by the time it was consumed; whereas, had it con-

Dr. R.  
Hutchison.

7 May 1900.

tained a small amount of preservative, it would not be likely to go bad.

6762. May I point out to you that the difficulty in regard to the custody of milk is a difficulty which ought to be met by other conditions? There, again, by the maintenance of preservatives to check that kind of thing, you are tending to preserve a condition of things which ought to be altered. I suppose you will allow that milk ought not to be kept in these unsanitary conditions?—Yes; I will grant all that, but then your plan, I think, will be Utopian. You cannot educate the poor people. I should think, in this country. From my experience of dealing with hospital out-patient mothers, it is exceedingly difficult to make them keep milk under favourable conditions.

6763. That is as regards the domestic supply, but I am talking about the vending of milk?—That is just the point. It may be all right when it is sold, but then, if it is kept under bad conditions in the house all the good of keeping it up to that time will be done away with, and it will go bad, whereas had it contained a preservative it would not be so likely to go bad.

6764. People are not likely to keep milk over a long time in their houses now?—In the summer time twenty-four hours is quite long enough to make it go bad, and that is quite a common time to keep it.

6765. We have had it in evidence that milk can be kept, when it is properly treated to begin with, by cooling and by filtration, for longer periods than twenty-four hours without detriment to it?—If it is kept in a cool place and covered up?

6766. Even if it is kept under ordinary conditions?—Of course, that is for the bacteriologist to say. Looking at the matter, without having any bacteriological experiments to help one, and having regard to the conditions in which it is likely to be kept in ordinary life, I should say that you are running a risk.

6767. What I want to ask your attention to is this—if it can be shown to demonstration that the effect of legalising the use of preservatives would be to prevent the farmer taking due precautions in his cow-house, in the cleanliness of his cows, in the cleanliness of the hands of his milkers, in the proper scalding of his cans, and in all those things which are proper to the proper supply of milk—if I say it is pointed out to you that the effect of the use of boracic acid is to preserve wrong conditions in these matters—would that modify your opinion?—I should have thought that that difficulty could be met by a proper inspection of dairies.

6768. That is already partially met, so far as relates to a proper system of inspection of the places where milk is vended; we wish to supplement an adequate system of inspection of the dairies by adequate inspection of the places where the milk is produced?—If you want to educate the farmers, of course, then, it might be bad to encourage them to use preservatives; but if you want to preserve the public health, then I think you are looking at the thing from quite a different point of view, and it might be advisable, perhaps, to allow the moderate use of preservatives. It would take some time to educate your farmer, and meanwhile the public health might suffer.

6769. Is there any evidence that the public health suffered when these preservatives were not in use to a greater extent than it now suffers?—There is absolutely no statistical evidence worth anything, I should think; nor would it be possible to collect it on a point like that. But I am quite certain that the amount of harm done to children from milk which has turned sour, or which is beginning to turn sour, is very great indeed—I mean the amount of diarrhoea that is set up by it. I do think that the moderate use of preservatives might be expected to

diminish such cases, by allowing the milk to be kept longer without going bad.

6770. I suppose that you are aware that we have had it in evidence—whatever the value of that evidence may be—that a considerable amount of infantile diarrhoea is associated with the use of boracised milk?—Yes. I believe that there is a certain amount of evidence to that effect, but, of course, I would not attribute that diarrhoea to the boracic acid necessarily.

6771. What would you attribute it to?—Probably there has not been enough of it added to keep the milk from going bad.

6772. But this is milk which is vendable, saleable milk, in which there is no suspicion on the part of the mother that it is sour?—Of course, the diarrhoea may be due to boracic acid. I am not saying it is not, but if you say that it is, you have got to exclude a vast number of other conditions. It is by no means all cases of diarrhoea in children that are due to bad milk.

6773. That is the point, but you rather led us to imply that a considerable amount of diarrhoea was due to milk which was on the point of turning sour?—There is a large proportion of diarrhoea that is due to sour milk, and there is a large proportion of diarrhoea that is not due to sour milk—that is, due to other conditions. That is all you can say.

6774. What precautions do hospitals take to ensure their getting a proper supply of milk?—They go to the good dairy companies.

6775. Do you mean as regards purity?—Yes. I believe in some hospitals they occasionally have an independent analysis made of the milk from time to time just to control it.

6776. Do they make any contract with the milk seller that he shall supply milk of a certain standard or quality?—As to that I really cannot tell you.

6777. Are you not connected with a hospital?—Yes.

6778. Which hospital are you connected with?—I am connected with the London Hospital, and with the Children's Hospital in Great Ormond Street; but the members of the staff do not necessarily know all these details about the providing for the catering of the hospital.

6779. You cannot say, then, of your own knowledge that in those two hospitals any precautions are taken in regard to the milk supply beyond dealing with reputable people?—I cannot say there is.

6780. Would there be any objection, for example, to entering into a contract with those milk sellers in the same way that the milk sellers themselves enter into a contract with the farmers?—There can be no objection at all, so far as I can see.

6781. (Dr. Bulstrode.) Having regard to the point we discussed as to the possible stultifying of medical treatment or modifying of medical treatment, would you advocate the course which Professor Thorpe has just suggested, of hospitals entering into a contract with their milk-supplying firms that no preservative should be added, or that if preservatives are added the nature and amount should be stated?—I think it would get over the difficulty you suggest, and would be quite a reasonable thing to do.

6782. With regard to infantile diarrhoea mortality, your thesis would rather point in the direction that, owing to the increased use of preservatives, infantile diarrhoea should now be decreasing?—Yes. I should think that one might expect that to happen.

6783. Do you know whether it is so or not—have you followed the growth and the variations of infantile diarrhoea together with the use of preservatives?—No, I have not.

Dr. G. F.  
Still.

Dr. GEORGE FREDERIC STILL, called; and Examined.

6784. (Professor Thorpe.) You have heard the evidence of Dr. Hutchison?—Yes.

6785. Do you agree with it?—It is too lengthy to include it all in one. There are some points, I fancy, on which I should perhaps hold rather different views.

6786. Would you kindly tell the Committee in what respect you do not agree?—Our experience has been entirely different. I have been noticing the effects of borax and boric acid on children only, while his experience includes adults. I have nothing whatever to do with adults at any time; so our observations are on entirely different lines.

6787. Of course, in that respect your evidence would be the more valuable to us, because we are given to understand that it is primarily in the case of children that the hurtfulness, at all events, of the use of ordinary preservatives in milk is likely to be occasioned; would you kindly tell us the results of your observations on children?—They are only with regard to the use of boric acid and borax in milk. With  $2\frac{1}{2}$  grains of boric acid and  $2\frac{1}{2}$  grains of borax to the pint—where these were present together in one pint of milk—I, as far as my experience goes, should say that the milk usually produces no harmful results whatever, but it does now and then produce some looseness of the bowels; at any rate, its administration is

Dr. G. F.  
Still.

7 May 1900.

followed by some looseness of the bowels; whether this is due to the boric acid or whether it is a coincidence it is very difficult to say. I am quite sure one has seen cases where it produced a definitely good effect; in fact, in one case it was found necessary to add borax and boracic acid to the milk, because the child could not get on without it. The child was passing undigested stools, and was suffering severely from flatulence; he was put on borax and boracic acid in the milk, and became distinctly better; these drugs were then stopped, but it was found necessary to give them again, and the child did better with them than without. I consider, therefore, that boric acid is not always harmful. In infants, I have seen it produce, or, at least, followed by some looseness of the bowels; I have not seen any vomiting produced by it. In older children I have used it in the treatment of epilepsy, adopting the same quantities purposely of boric acid and borax, that is to say,  $2\frac{1}{2}$  grains of each in half an ounce or an ounce of water, given three times a day. This amounts to rather more than would be taken in the milk, for they would not have taken three pints of milk daily at that age. I am quite sure the borax has done good in epilepsy; I have used the ordinary bromide mixture alone first, and have obtained a certain improvement. This, however, has been only partial; borax has been added to the mixture, and then there has been a very definite further improvement, if one may judge by the parents' account. Dealing with out-patients one has to judge chiefly from these accounts, but, as a rule, parents do not give a more favourable report of their children's progress than they should, the tendency rather is to go the other way. They have been satisfied that the number of fits has been much less with the borax than with the bromide alone. I have no doubt it has done good. Boracic acid has then been added to the mixture, and seemed to have a further good effect in reducing the number of fits, but some of the cases have got looseness of the bowels, and one has had to stop the boric acid. I am, therefore, inclined to think that boric acid may produce looseness of the bowels, perhaps more often in infants than in older children, but occasionally in both of them.

6788. If these things have the specific effects that you allege, surely those effects should be under the control of a medical man, and they should not be left to the vagaries of a milk seller?—I was simply referring to the therapeutic questions that have been asked of previous witnesses. I was not dealing with the question whether these preservatives should be present in milk; I was directing myself to the physiological question.

6789. What is your point about that?—With regard to milk I should say most emphatically that no preservatives should be used if you can guarantee the milk being kept from decomposition otherwise. As far as I know there is only one dairy in London that at present partially succeeds in doing it. I know that the big dairies do not succeed; we have our milk supply at Great Ormond Street from Welford's, and this milk in summer, in spite of all precautions, is sometimes sour by the time it reaches the children; so presumably one of the best dairies in London is unable to supply at present, or does not supply, milk which does not decompose very shortly after it is supplied in the summer.

6790. Is that due to anything in the conditions under which it is kept in your hospital?—It is certainly kept under very much better conditions in our hospital than it is in the homes of the poor. I quite agree with Dr. Hutchison that at present it is absolutely impossible to hope to get the homes in such a condition that the milk shall not decompose. At our hospital the milk, when received, is placed in a large so-called steriliser, but we do not attempt sterilisation; it is supposed to be raised to 155 or 160 degrees; it is kept at this temperature for twenty minutes, and then it is drawn off into large cans which are at once covered up, and the milk is then delivered to each ward and kept in a cool place until it is used for the children. That is considerably more than is usually done in any private home, at any rate in the homes of the poorer classes; and yet, with all those precautions, we are very apt to get bad milk in the summer. I have seen one or two epidemics of diarrhoea there in the summer where it was traced definitely to the milk having gone bad before it reached the children.

6791. In what other points do you differ from Dr. Hutchison?—I do not know that it is exactly a point of difference, because I think that Dr. Hutchison would agree with me that if it were feasible to supply milk which contained no bacteria, or so small a number of bacteria as to be harmless, this would be vastly preferable to sterilising or pasteurising. My own experience of children has impressed me very strongly with the idea

that a great many of the ailments of upper-class children particularly—infants, I mean—are due to sterilisation and even to the boiling of the milk. I believe that it has been greatly overdone. One sees infants who are not getting on, they are not gaining weight, their nutrition is suffering, without anything very evident to account for it, but if you take them off sterilised milk and put them on fresh milk, and see that the milk is not raised to boiling at all or is only kept at a pasteurising temperature for as long as ten minutes, these children rapidly improve. I believe for this reason that sterilising or pasteurising is not the best thing to be done. I believe the ideal thing would be to sterilise the udders of the cow and to sterilise the milkman's hands, and to restrict antiseptic precautions in dealing with the milk, as is done at present so far as is possible by the Walker Gordon Dairy. Their milk will certainly keep longer than most milk after being supplied; and, as far as I know, this is the only dairy in London that is even so far successful. But milk supplied in that way is altogether too expensive for ordinary use; it is quite beyond the means even of the middle class.

6792. What change comes over milk by sterilisation or pasteurisation which affects its nutritive value?—It is not known why scurvy rickets occurs in infants kept on sterilised milk.

6793. Rickets?—I would rather say infantile scurvy. Infantile scurvy certainly comes from the use of sterilised milk or milk that has been boiled a long time—not necessarily raised to a very high temperature. I believe that short of getting infantile scurvy infants suffer from conditions of mal-nutrition when they are fed continuously on milk which has been kept at a high temperature for even a short time, and that even prolonged pasteurising is harmful.

6794. What is infantile scurvy otherwise traceable to? It is not understood why milk which presumably has not been materially changed in its composition—it is the same food after the sterilisation as it was before—brings about scurvy?—The reason is unknown; but the fact remains clinically that it does. I believe it is absolutely unknown what is the one element the lack of which produces scurvy.

6795. Is it generally recognised in the medical profession that infantile scurvy is traceable to sterilised milk?—It is generally recognised that it is traceable to sterilised milk. Of that there is no question. It is a well-recognised fact.

6796. How was it produced when milk was not sterilised?—It can be produced by almost any of the patent foods.

6797. Is infantile scurvy a modern disease?—It has become more common in modern times—it is increasing. This, of course, is not in my own experience; it is simply a matter of other people's experience much older than I am, but this disease is said to be definitely on the increase.

6798. And you connect it with these patent foods and the sterilising of milk?—Yes. I believe that almost all infantile scurvy in the upper classes is due to sterilised milk and to these patent foods.

6799. (Dr. Bulstrode.) You have, then, certain objections against the use of both sterilised and pasteurised milk?—Yes.

6800. As a medical man?—Yes. I do not object to pasteurised milk so much as to sterilised milk. I think both would be very much better omitted, but the pasteurisation is far less harmful. The harmful results of sterilisation are much more than a matter of opinion; that has been confirmed by years of experience.

6801. We have had it in evidence before us that the milk supply of large towns—indeed, the milk supply throughout England—could be very well carried out if the procedure as regards sterilisation which you mentioned and also the application of cold and refrigerating were properly resorted to. Do you know any objection from your medical experience to reducing the temperature of the milk to freezing point?—No, I see no objection to it, but I think it is quite conceivable that it might produce scurvy at the other end of the scale. At present the view is that the scurvy is produced by the absence of some living element or other in the milk, and I suppose it is conceivable that freezing might have the same effect as boiling. But I have no experience, and I do not know that other people have, on the point, and I think it would be impossible to say at present. Otherwise, I think there is no objection to it.

*Dr. C. F.  
Still.*

7 May 1900.

6802. You think moderate cooling would not have that effect on it?—Certainly not, I should say.

6803. Is cream used much in children's hospitals at the present time?—Not very much; but I suppose it is used a great deal more there than in the adult hospitals. In Great Ormond Street we use it.

6804. Would you tell the Committee what you use cream for chiefly?—Cream is given usually for children who are suffering from marasmus where it is desired to increase the amount of fat in the food; it is not used specially for any particular disease that I know of; it is generally used for a child that is wasting.

6805. Do you see any objection to the use of preservatives in cream?—I think the same objections would apply there as in the milk. I think the possible irritating effect of preservatives is to be borne in mind, and I think also it is quite possible that there are chemical changes which might occur without their being appreciable by the nose or by the taste in cream kept by preservatives.

6806. You heard me discussing with Dr. Hutchison as to the manner in which possibly the indiscriminate use of preservatives might prejudice the position of a prescriber in a hospital or outside; would you give us your views as to that?—I am inclined to think that it might sometimes be serious, but there are so few drugs used as preservatives which are in common use for medical prescribing. Salicylic acid, of course, is important, and the benzoates.

6807. Salicylic acid, borax, and boracic acid?—Yes; but then, borax and boracic acid are comparatively seldom used; boracic acid, I suppose, very rarely, and borax not commonly. The benzoates and the salicylic acid, I should think, are the only common ones; formalin is practically never used internally.

6808. Salicylic acid is commonly used?—Yes.

6809. Do you see any objection to the indiscriminate use of that?—I think it would be distinctly objectionable, the physician would never know quite what does of the drug the patient was getting; it may be in the milk in any unknown quantity.

6810. Do you not think it is a very important matter for the medical profession, quite outside the question of public health, to know whether their patients are already taking something of which they propose to prescribe relatively small doses?—I think so. If there is any there at all it should be accurately known what the quantity is, and it would be much better if there were none there.

6811. Do you think the milk supplied to all hospitals should be examined as to the presence or absence of preservatives?—Yes, I think it is most desirable, but it cannot be done at the hospitals in the ordinary way; there are many hospitals that could not manage it.

6812. It could be done outside by arrangement?—Yes.

6813. With regard to the milk which you obtained from Messrs. Wellford, you say it frequently decomposes?—In summer, but not at other times.

6814. Do you know whether any preservatives have been added to it or not?—So far as Professor Thorpe's observations on our milk go, there has been none in the specimens supplied to him—fifteen specimens—I think I am right in saying that none of them contained a preservative. The butter has contained borax from 17.4 up to 47.6 grains to the lb. That butter has been used indiscriminately for the children—not all the children get it, but a certain number—and no bad effects have ever been traced to it.

6815. They would not consume much?—They would consume very little indeed, and only a few of them get it.

6816. Do you see any objection on general principles to the use of antiseptics in the stomach when they are not called for? You heard what I said to Dr. Hutchison as to the effect of preservatives on vegetable organisms—micro-organisms—assuming that the preservatives destroyed the life of these micro-organisms, do you see any danger to the gastric cells from them?—I really have no evidence to give upon that point; it is simply a matter of opinion. The only one that seems to me likely to do any harm is formalin, and I am very doubtful whether formalin may not do considerable harm.

6817. In what way?—By its action upon the stomach. I should think myself it would interfere with digestion if administered for a considerable time; I should think it would damage the cells and so interfere with the digestion. I have felt very chary in letting the children have anything that contained formalin.

6818. Do you think experiments in vitro would guide one at all as to what one might expect from the use of formalin in the human economy?—No.

6819. Not at all?—No.

6820. You would not attach much importance to those experiments?—No, I should not.

*Dr. E. Hope.*

*Dr. E. HOPE, called; and Examined.*

6821. (*Professor Thorpe.*) You are Medical Officer of Health for Liverpool?—Yes. I have been five years Medical Officer of Health, and previous to that I was about ten years Deputy Medical Officer of Health.

6822. You have some opinions to offer to the Committee on the subject of the use of preservatives and colouring matters in food, I believe?—Yes. The Committee has been good enough to ask me to express my views on some of these points.

6823. Will you kindly tell us what you have to say?—I wish to say, in the first instance, that I am quite alive to the importance of preserving the food supplies, as far as they possibly can be preserved; and in view of the very large amount of waste which arises in the food trades, one welcomes any means that can be safely made use of to avoid waste of this description.

6824. In what sense do you use the word "preservative"?—I use the word in the sense in which this Committee is now dealing with the matter—in the sense of chemical preservatives, but associated with chemical preservatives is cold, and we find, as I shall presently be able to give you, evidence that chemicals are used as well as cold very frequently, so that the two means of preserving are associated in that way; cold alone, I think, receives its best illustration in the Copenhagen system, which, however, is perhaps not applicable in our country.

6825. Why is it not applicable?—I am afraid that ice is not so abundant, not so cheap, and I imagine that the inauguration of a system such as that at Copenhagen would involve a very large amount of capital, because there is nothing, so far as I know, in this country that at all approaches it or that has ever been run on those lines.

6826. Are you aware that an influential milk supply

association in Manchester is beginning to run a supply on the Copenhagen system?—Yes, I am aware that there was, I think, two or three years ago, some system of that sort inaugurated, and efforts were made at or about the same time to employ the system in Liverpool. So far as Liverpool was concerned, it was absolutely without success; and, in regard to Manchester, I have no recent information as to the extent to which the system has been successful. I have no doubt at all that it has, to a limited extent, succeeded.

6827. You are doubtless aware that a considerable proportion of London is supplied with this milk, without the use of any other treatment than cooling?—Yes, I am quite aware of that; but what I meant by quoting the Copenhagen system was the system under which, from the very commencement until the distribution of the milk at the door, the milk was practically cooled and kept cooled below the point of putrefaction, or decomposition, solely by the means of block ice. That is really what impressed me so much when I was investigating the Copenhagen plan—the abundance and the constant use of ice.

6828. You are aware, of course, that the limited application of cold such as obtains in the case of a considerable amount of milk which comes, at all events into the better ends of this city, is sufficient to maintain the milk sweet during the time that it is necessary to keep it for the purpose of consumption?—Quite so. I am not adversely criticising that practice at all; I think that that is a remarkably good one. That system, more or less, I suppose, obtains throughout the whole country. If one takes Liverpool as an example, we find that the use of any chemical preservative is so rare as to lead one to conclude that it is not necessary at all with ordinary care and cleanliness; I am very strongly of that opinion.

6829. Then we may gather that you see no necessity

at all for the use of the so-called chemical preservatives in the milk supply of a community?—I see absolutely none; and, in support of that view, I would quote the fact that the vast proportion of the milk sold in Liverpool is absolutely and entirely free from any chemical preservative. I think that fact is one which indicates that there is no necessity to put it in if due cleanliness and care are observed.

6830. Will you kindly tell us, before you pass on to the other subjects, whether you have anything more to say on the milk question?—I would say this, on the milk and cream question, that in those cases where preservatives have been added, there is a very grave risk of injury to the health of young infants who may be fed upon milk containing these preservatives, both in regard to milk and in regard to cream, because the chemical preservatives which will check putrefactive changes in milk or cream will also check the processes of digestion. You no doubt are aware that experiments have been tried by feeding young kittens upon milk containing different proportions of preservatives; these have been carried out extensively in Liverpool at the laboratories there, with the result that the kittens fed upon milk containing boric acid or formalin have died practically from starvation, whilst others equally healthy to start with, and fed upon ordinary milk, have grown and increased in weight, and remained in health.

6831. I suppose the great bulk of the milk that comes into Liverpool has no very considerable distance to travel?—About one-half of it has a considerable distance to travel; about one-half of the total supply in Liverpool comes from the country—Lancashire, Cheshire, and Shropshire.

6832. Two at least of those counties are near—of course, Liverpool is in one?—But still the milk comes from distant parts of the county; it does not all come from the immediate neighbourhood—in fact, I should think that most of it comes from some considerable distance.

6833. Not more than fifty miles, I presume?—Say about fifty miles.

6834. Have you anything more to tell us as regards milk or cream?—I should like to say that the use of preservatives in cream is very much more common indeed than it is in milk. Why it should be so I really do not know, but the fact remains. There is this peculiarity in connection with the use of preservatives in cream. It seems to have been going on for so long, and the practice has been, I will say, never found fault with—it has perhaps never been detected; consequently we find that the best makers or preparers of cream—I will not say makers of cream, but vendors of cream—send out their cream with those labels, some of which may be familiar to you—I have no doubt they are. (*Handing in pots of cream.*)

6835. Is this a character of cream which is mainly sold by grocers?—This is supposed to be a pure cream. This pot comes from Lord Vernon's dairy, and it has on it that it has a slight amount of preservative added to aid its keeping qualities. "This is necessary and usual," it states on it. It may be usual, but I do not consider it necessary.

6836. Is that a character of cream which mainly finds its way into the hands of grocers, or is it sold by dairy associations?—By both. The impression that one derives from reading that label is that because a thing has been going on for some years without its danger being demonstrated, therefore it may be legally continued. The same remark would exactly apply to milk. If the addition of preservatives to milk had not been promptly challenged, no doubt the preserving of milk in that way would still have gone on.

6837. It is stated on this label that the practice of adding the preservatives has been approved by the leading medical and scientific authorities; are you able to corroborate that statement?—No, I am not; I should be disposed to controvert that entirely. With regard again to milk, which is the most perishable of all articles of food, I take it, or as perishable as any other article of food, the sale of milk without preservatives shows that the preservative is not a necessity. It may be made out that the public want preservatives put in; it may be alleged that the public want them.

6838. By whom is that alleged?—By those who put it in—by the vendors.

6839. Is there any proof that the public desire to have preservatives in their food?—No; I say the proof is on the other side, from the fact that the public buy their milk without preservatives, and when preservatives were

added complaints arose, followed by prosecutions, when the addition of the preservative was desisted from, and the sale of the genuine milk was resumed without any trouble or any difficulty. Therefore I contend that the use of preservatives in milk is an unnecessary thing.

6840. Now, with respect to the use of preservatives in other articles of food, what have you to tell us?—We find from the analysis of a variety of things that the use of preservatives appears to be becoming more and more extended and common in butter, ham, bacon, pork, fish, margarine, pork-pies, sausages, and so forth.

6841. Have you the same objection to the use of these articles that you have to their use in milk?—No, I have not so strong an objection. I do not think it is a desirable thing, but I have not the same objection that I have in the case of milk and cream, because these other articles are used by adults and people of stronger digestion, and the mischief may not be so accentuated in their case as it unquestionably is in the case of young infants. I should like, if I may, to revert to the milk point for one moment to quote just one domestic incident. A lady complained to me that she had made arrangements with her milk dealer to give him twice the amount he asked upon the condition that he should send her nothing but pure milk. At her own cost and charges she had the cows examined by a veterinary surgeon to see if they were all right; in fact, she wished to spare no expense to ensure pure milk for one of her infants. Things went on very well until one day the infant was taken violently ill. Nothing had been given it but under her own supervision. She at once went to the milkman and asked what he had been sending, and he admitted that he had put some boracic acid in the milk—he admitted it at once. I mention that as an instance—one of course not of many—in which mischief may be directly traceable to the use of a preservative in milk.

6842. What have you to tell us as regards the use of preservatives in other things?—In jam and in British wines what I wish to draw attention to is this, that even assuming that a minute quantity is necessary and harmless in those things, many of the manufacturers are exceedingly lax, more especially in regard to the quantity that they put in British wines. If it is admitted that 7 grains of salicylic acid to the gallon of British wine is necessary to preserve it, there is no reason why 150 grains to the gallon should be put in.

6843. Is that an actual case?—That is an actual case. That is what we find by our analyses; in one sample we find 7 grains to the gallon; in another one 150 grains, or even more than that. With regard to jam I have here an analysis of three samples of strawberry jam; one is entirely free from salicylic acid, the next one contains 0.28 of a grain to the pound, and the third one contains 1.75 grains to the pound; so that of those three one has none in it, the second has a small quantity, and the third has nearly ten times as much—and this is with precisely the same article. Therefore, even assuming that it is necessary—which I do not assume, because in one instance it is sold without any—but assuming that it is necessary to put some in, I take it that the minimum will meet all requirements; there is no need to put in a quantity which might be prejudicial, because jam is an article which is eaten by people of delicate digestion—young children, and so on.

6844. But your evidence would equally well go to show that the minimum required is zero?—Quite so, that is the position that I should maintain, that if an article can be sold, and is sold, and largely sold, without any, I fail to see where the need comes in for putting in a preservative. A sample of raspberry jam contained 4 grains to the pound—one could go on steadily increasing. It appears to me that if it be granted that some small quantity is necessary that the manufacturers are not careful to observe what is the minimum.

6845. They have no knowledge probably on the point?—Probably not.

6846. Have you exhausted all you have to say respecting the use of preservatives?—In certain prosecutions which have been brought about the defence has been that the quantity of preservative is not enough to endanger health. That is a moot point. We believe from experiments upon young animals that it is enough to endanger health. We cannot go on experimenting upon human beings in the same way that we can experiment upon kittens; we cannot employ means to feed young children only upon adulterated articles. We know that at the very commencement of the experiment the child would become ill, as in the case that I have just quoted to you, therefore we have no right at all to assume that the

Dr. E. Hope.

7 May 190

Dr. E. Hope.

7 May 1903.

use of chemical preservatives is not attended with injury to the consumer. But that has been the defence, and an ingenious defence also has been put forward which no doubt has weighed with the Bench, namely, that these things are used in medicine, and larger doses are given in medicine than would be given here; but what one would point out is that to give a dose of physic under certain diseased conditions of the human body is one thing, and to administer drugs at odd times with every meal when they are not necessary is a most objectionable proceeding.

6847. Now, what have you to tell us about colouring matters?—With regard to the colouring matters sometimes, I presume, they are merely for ornamental purposes, and probably harmless, that is, in sweetstuffs and sausages. They are given to make the article attractive not to imitate anything else, but to give it a bright red colour, or for some such purpose in the case of foods of that description. A number of colouring matters I have got possession of, and caused analyses to be made of them. The commonest, which is usually used for sausages—German sausages especially—consists of borax, a red coal tar dye of the sulphonated class, with salt or saltpetre, ground rice or bread crumbs. Then, Armenian bole is another common colouring matter.

6848. What does that consist of?—That consists of oxide of iron, with silicious matter. Then, the use of a material called "smokene" is not uncommon.

6849. What is the composition of that?—Smoke-ne consists of borax, salt, creosote, and red coal tar dye. Whether or not that is used in such a manner as to cause injury to health is perhaps doubtful. The dye itself I am assured by chemists is an exceedingly objectionable one, but the use of it is to brush over hams and tongues and things which are usually smoked, and the consequence is that you see common unsmoked badly prepared articles of food with an appearance that one might see in a first-class purveyor's establishment, simulating the appearance of splendidly dried fish, tongues, and so on. Smoke-ne undoubtedly has its uses and advantages, but the use of a colouring matter such as this I should say would border upon the fraudulent.

6850. You mean it would lead a consumer to suppose that the thing had been adequately cured by the ordinary operation of smoking?—Yes.

6851. Whereas it might have been imperfectly cured and covered over with this dye so as to simulate a proper appearance?—Yes, with this stuff which they call smoke-ne. Another colouring matter, if it can be so regarded, really is or was an adulteration. The object of it is to change the colour and appearance of the article. I refer to the use of glucose, with common black treacle, to dilute down the dark colour and make it resemble golden syrup. That matter has been settled practically in Liverpool now by a prosecution. The persons prosecuted appealed to the Quarter Sessions against the conviction at the Police Court, but the conviction was upheld; so that the sale of a mixture of treacle and glucose for golden syrup is not likely to be continued. However, that is an instance in which there was the use of glucose actually as a colouring matter as well as an adulterant. Then the use of burnt sugar with dilute acetic acid to resemble vinegar may also be quoted as a use of colouring matter.

6852. In that case, although it is fraudulent, it is not directly injurious?—It is not directly injurious. One objection to the use of colouring matters is that they conceal the inferior quality; another objection is that they conceal staleness or dirt. For example, dirty rice, coloured with a yellow coal tar dye—the yellow colouring matter taking away the dirty appearance—is used to make what are called egg powders. Similarly the use of colouring matters with milk has come under our notice, the object of the dye being, of course, to make the milk a little richer in appearance.

6853. These egg powders are mainly of the character of baking powders, I presume?—Egg powders are baking powders, or are generally understood to be so. I should like to call your attention to one or two points in connection with baking powders. There is upon the market a powder which I will hand in, called "Egg Food," and it really is a preparation of a dried egg. I do not say that it is all that is claimed for it, but it is an albuminous food, and the chemical analysis of it is that it weighs 83½ grammes and contains about 14 grammes of albumen—about as much albumen as could be got from two eggs—and as much fat as could be got from half an egg. Therefore, that is an albuminous food, and could be used as an albuminous food, of course. But there is another

powder upon the market called "Egg Powder," which is made up of tartrate of potash, bi-carbonate of soda, I suppose, and things of that description. Here are two others, both claiming to be complete substitutes for eggs (*handing in specimen packets*).

6854. Do you say that this which is labelled "Pegram's Egg Powder" is not really an egg powder?—It is not an egg powder at all, and it has no connection with eggs whatever—absolutely none. Cases have come to my knowledge in which poor and ignorant people have purchased these egg powders under the impression that they were a complete substitute for eggs, and with that idea they have actually fed their children on them. It is a most extraordinary thing, but that fact has come to my knowledge. One would hardly conceive it possible, but it is the case.

6855. I see on one of the samples which you have handed in the manufacturer distinctly states that it is not made from eggs?—Yes, that was sent to me by the manufacturer to know if it was a label which would be approved of—would it protect the vendor in selling the article? He marks it as "A complete substitute for eggs, but not made from eggs." Of course, we say, "No, it will not protect him." I brought that to show you.

6856. That has not been put on as a result of any prosecution, has it?—Yes, it has. They say: "What shall we put on? Will that suit you?" "No," we say, "it will not."

6857. May we gather that there has been a prosecution at Liverpool for selling this substance as being made from eggs?—Yes.

6858. And as a result of that prosecution the manufacturers propose to put on that label?—Yes. I should like to draw your attention to this fact—it is a trade question, and I do not wish to mention manufacturers' names, as there is no advantage in that.

6859. Before you pass on from that point, may we ask whether the other samples are like this? This one is called "Bird's Concentrated Egg Powder"?—That is the same as this.

6860. That also has nothing to do with eggs?—Absolutely nothing.

6861. Has that been the subject of a prosecution?—No.

6862. Is that sold in Liverpool?—Yes. I do not think that particular one has been the subject of prosecution. Others have; new ones crop up from time to time.

6863. That is not protected by any label?—No. That contains a yellowish colouring matter which I suppose is added with a view to forward the idea that there is some connection with eggs. I have an interesting correspondence bearing upon these colouring matters. The manufacturers are not the people whose names appear on these; the manufacturers make the article and it is sold by different firms—wholesale firms or other firms.

6864. Each puts his own label on?—Yes. When a prosecution was taken against these people their defence was rather curious. I will read a letter, if I may, from the manufacturers. It is a letter addressed to their solicitor who was defending them in the prosecution:—"Herewith a couple of these egg powder packets. The adulterant for these things and baking powders was alum." You see they considered that because they do not put alum in they may sell it under any designation they like.—"As there was no alum in these, we thought they would be all right. The labels were printed last year, before the new Act was passed. The firm in question are most respectable people, and have not the slightest idea of cheating anyone over it. They sold a great number of packets at Christmas, so it was evidently what was wanted." You see, that is one of the fallacies that those who use preservatives and colouring matters fall into. The public, not knowing what the things contain, buy the article, and the manufacturers then say there is a demand for it. The public will have it, and we must give it them. "People like ourselves, who are constantly making things like this up, get so in the habit of looking on egg powders, etc., as being mixtures, that it does not seem possible to us that anyone else will expect to get dried eggs, if there is such a thing." I do not see, if you say it is a substitute for eggs, why the same complaint may not still be made as on the summons—that it contains none of the nourishing properties. If it is a substitute it ought to substitute the qualities in respect to nourishment. That is a most extraordinary letter to come from a manufacturer. They are most respectable firms. It is merely an indication of the lack

of knowledge of the people dealing with these things rather than of anything else.

6865. Still, it is not perhaps strictly relevant to the subject of preservatives; it is a case rather of the misdescription of an article, is it not?—At the same time, they do contain colouring matters.

6866. That is to help off the deception?—Yes. People associate yellowishness with eggs, and it is with that idea that a slight amount of yellow dye is put in.

6867. Have you anything more to tell us?—I should like to make a suggestion, if I may do so, in regard to the use of colouring matters and preservatives, namely, that whenever they are used, as, for example, in these cases, that the fact should be stated—a simple label should be put upon the article, first, stating the nature of the material used; secondly, the quantity of it; and, thirdly, the date on which the material was added. I can see no objections to such a course, but I can see every advantage, that the public would then know exactly what they are getting, how much of the article they are getting, and how long that preservative has been in the material. I do not know whether it would come within the scope of the enquiry to refer to articles which are sold as sterile and which are not sterile—not bacteriologically pure.

6868. But which contain preservatives?—Yes.

6869. Certainly?—Some do not contain preservatives, and are sold as sterile, but are not sterile; those, I presume we have no concern with here. But I take it that the sterility should not be owing to the presence of the preservatives. It should be owing to the cleanliness and carefulness of the method of preparation. If preservatives are allowed to be put in, you may still get a dirty and contaminated article, but a chemical preservative will be added which will keep it sterile.

6870. What class of things have you in your mind where substances are actually labelled sterile, which owe their presumed sterility to the presence of preservatives?—Milks are the articles that I have in my mind, and tinned milks.

6871. Are they distinctly labelled as sterile?—Sometimes they are; they claim to be, but by no means always. There are examples in which they claim to be sterile, but they are not sterilised.

6872. The word sterile to you I suppose connotes a thing having been treated at a relatively high temperature?—Yes, and as a result of that that it is bacteriologically pure, and has no organisms growing in it at all.

6873. It is of the essence of sterility that it should have been treated by the influence of a high temperature?—Yes, that the sterility should not be obtained by the addition of preservatives.

6874. By the addition of chemicals?—Yes.

6875. It would be a false trade description in fact to apply such a term to sterility produced in any other way than by the use of a temperature sufficient to make it bacteriologically pure?—It ought to be so. Then I wish to bring to the notice of the Commission the importance as a method of technical procedure in obtaining samples, that persons conversant with the business should be employed.

6876. You refer now to the inspectors?—Yes, now and again persons who are not familiar with the methods undertake examinations in an amateur fashion, and the consequence is that they may arrive at conclusions which are very misleading. It is a practical point—a point of administration; but an instance came under my notice in which a gentleman himself obtained and caused to be examined a number of samples of milk, and most of those samples were found to contain preservatives. So he at once jumped to the conclusion that he had got a fair sample of the article supplied to the public, and published his results. But inquiry showed that all of these things came from one and the same source—which illustrates what the Local Government Board, I believe, have already had under their notice—namely, the importance of having trained inspectors to obtain these samples in order to get fair average samples, and not a number out of one place.

6877. Do you mean to imply that it is not the custom of the local authority to employ competent men?—I do not wish to do more than emphasise the importance of obtaining trained assistants in this matter.

6878. What else have you to say?—Another matter that is of increasing interest by reason of the increasing trade is the use of borax in meat—pork more especially. This is not a use which I have any reason to think is ob-

jectionable at the present time, but the magnitude of it is a sufficient reason for bringing it before the Commission. Up till within the last two years very little fresh pork was imported from America into Liverpool, the reason being that the freezing process destroyed the appearance of the pork, and made it unsightly, and there was very little, if any, sale for it. Now, instead of freezing it to such a low temperature as to make it unsightly, the pork is kept in a temperature of about 33 or 34 degrees, or a little higher than that—chilled, as they call it; sometimes I know it is lower than that. The object is to chill it. In order to prevent any decomposition, the pork, which is packed in cases about 50lbs. weight, is sprinkled over with borax or dipped into solutions of it—usually the powdered borax is sprinkled over it; it is then put into the cooling chamber, and is brought over. But the trade is a very large one. Last year it appears that something like 36,000 carcasses of pigs were brought over to Liverpool alone from America treated in this way, but up to within the last year or two there was none brought at all; so you see there is a rapid development of a new industry, and, so far as I am able to ascertain, there is no objection to the practice. I think there is a vast distinction to be drawn between the use of a preservative in that way and the use of a preservative in milk, or in cream, or in any other way.

6879. Have you anything more to add to what you have already told us?—There is just one more fact I wish to call the attention of the Committee to—that is, that the Corporation of Liverpool, amongst other Corporations, are establishing depôts for the sale and distribution of milk specially prepared for young infants. The milk is humanised and prepared in a way that I need not detail, and is distributed in such a way that the child shall get a pure humanised milk. What I wish to point out in regard to that is, that the Liverpool Corporation and the other Corporations and private dealers who are following on the same lines must get their milk from wholesale dealers. Now, if the wholesale dealers before sending the milk to their customers put a preservative into it, and that milk with a preservative in it is prepared for young infants, the presence of that preservative will do the most serious mischief. You may say that every sample should be examined and analysed, and so on; that may or may not be practicable; but there is no doubt whatever that if a chemical preservative is put into milk which is destined for young infants very serious mischief will result.

6880. As regards your Corporation, however, they could take steps to protect themselves against the use of preservatives?—Quite so; we should always endeavour to protect ourselves against foreign constituents in the milk that we get; but we wish not only to protect ourselves in that way, but to protect ourselves now by emphasising the danger which will result if milk dealers are permitted or countenanced to put a preservative of this kind into the milk. It may be that the best of means may sometimes fail in the way of detecting preservatives in milk; it may be that samples are not always examined; there are a hundred things that may occur, and so we wish also to safeguard ourselves at the very source.

6881. When you say these are got from wholesale dealers, I presume you mean dairymen who stand between you and the farmers?—Either that or the farmers themselves; we may get it direct from the farmers, or we may get it from the wholesale dealers who stand, as you say, between us and the farmers.

6882. As a rule the wholesale dealers enter into contracts with the farmers?—Yes.

6883. And the contract specifies, as a rule, a certain limiting value of butter fat, and frequently that the content of non-fatty solids shall be not below a certain amount; it stipulates further that it shall be the whole milk of the cow, and that it shall not contain preservatives?—Sometimes those clauses are added, but not always. In our contract for our city hospitals, for example, we ask for "pure new milk"—I think that is what we ask for—and then we have a clause relating to the tuberculin test, but that is foreign to the point. We assume that in asking for pure and fresh milk we get pure and fresh milk.

6884. What steps in your hospital do you take to assure yourselves that you do get pure and fresh milk?—Very frequent analyses, but we cannot analyse every canful of milk that arrives—that would be an impossibility.

6885. Those analyses, I presume, would be entrusted to Mr. Collingwood Williams, would they not?—Yes, and Professor Campbell Brown.

Dr. E. Hope.

7 May 1900.

*Dr. E. Hope.* 6886. Would they report the presence of preservatives?—Yes, they report the analysis of every sample taken and every detail.

7 May 1900.

6887. Including the preservatives, if present, and the amount?—The amount and the nature of it.

6888. I presume they would also report any deficiency in the normal constituents of milk?—Yes, they give us complete analyses. What I was emphasising is that there may come supplies of which we do not get a sample. We do not take one every day. What we want to object to is having preservatives put in at all.

6889. (*Dr. Bulstrode.*) In relation to the Liverpool Fever Hospital, are precautions taken there against the use of milk containing preservatives?—Yes, those precautions which I have just mentioned—by taking frequent samples on delivery. Samples are taken by inspectors under the Food and Drugs Act on delivery at the hospitals.

6890. At the fever hospitals?—Yes.

6891. Do you regard it as a matter of importance that milk containing chemical preservatives should not be supplied to a fever hospital?—Yes.

6892. For what reason?—Simply because we believe that these chemicals interfere with the digestive processes, and in the case of sick people, people with typhoid fever, and so on, we wish them to have nothing but natural food.

6893. Would you see any danger in prescribing milk with a large quantity of boric acid for cases of scarlet fever and kidney disease?—Yes, I should object to the administration of any drugs of any kind or description to patients except under the guidance of the physician.

6894. Do you think the physician himself ought to know whether the drug which he is prescribing is already contained in large quantities in the food which the patient is taking?—Yes, I certainly think he should know exactly what is the composition of the milk which is given to the patient.

6895. Do you think there is a danger at the present time of the prescriber rather stultifying himself?—Yes.

6896. Your experience, I take it, goes to show that a population of getting on towards three-quarters of a million can be supplied quite well with milk without the use of preservatives?—Yes, that is the fact.

6897. And also without the use of refrigerating?—Yes, that is so.

6898. Therefore ice would not be necessary; so, supposing the use of preservatives were prohibited in milk, that would not involve any costly machinery for the production or the storage of ice?—I do not know that it would, but I should like to say this: that the supply of milk in the city of Liverpool, and the milk trade generally, is improving. It is now well in the forefront; it is keeping pace with the times. I have no doubt whatever that if additional machinery were necessary it would be provided by the dealers.

6899. If you had to choose between sterilisation and chemical preservatives in a limited degree, which would you select for milk?—Sterilisation without question.

6900. We have been told this morning, just before you came into the room, that infantile scurvy was increasing considerably, and that in the opinion of the medical profession that increase is due in large part to the use of sterilised milk?—I have never heard that before.

6901. You never heard that opinion before?—Never.

6902. It was attributed to the use of sterilised milk and prepared food generally?—I can quite imagine that mischief may result from artificial foods the composition of which is doubtful, but I have never heard any such thing raised in regard to the use of sterilised milk or humanised milk; in fact, there is strong evidence to the contrary from St. Helens if you wish that, where they have already established a sterilised, humanised milk depot with very satisfactory results—so satisfactory that the Corporation of Liverpool are imitating it.

6903. Would you have been in a position to ascertain whether the use of that sterilised milk was giving rise to any bad results among children?—I have personally made the inquiries. I have been over to St. Helens more than once, and have had frequent interviews there and in my own office with the Medical Officer of St. Helens, and his results are entirely favourable.

6904. To what extent, do you know, is sterilised milk being used in St. Helens?—I believe in the summer time they were supplying about 100 families a day—I do not think more than that; but they were supplying it in the most careful manner, every record being kept of the pro-

gress of the case. It was not simply sold as an ordinary dairyman would sell milk over the counter, but the children were recorded, their weights were taken, and their progress noted.

6905. And no bad results have so far been observed?—None that I have been able to ascertain or have heard of, or even heard hinted at.

6906. How long has this experiment been going on for?—Since last year.

6907. Continuously?—I should think for about twelve months now.

6908. You would rather expect that if any great harm is likely to occur from the use of chemical preservatives we should have cases on record where we might have had outbreaks of baracic acid disturbance, or salicylic acid disturbance, or something of that kind?—The difficulty is this, that the symptoms of baracic acid disturbance would so closely simulate those of ordinary aggravated indigestion that I should hardly expect that definite notice would have been called to it, more especially with young children—their ailments are so difficult to trace very often.

6909. You do not think it might have been observed in connection with some individual milk round on a certain occasion when, owing to carelessness or what not, an undue amount of preservatives was added?—That would involve the co-operation and careful attention of the mothers, and I doubt if there are many who are feeding their children in precisely the same way as in the case that I quoted, in which clearly the mischief there was traceable to the preservative.

6910. In that case was the preservative added on the one day in which the child was supposed to have been ill?—Yes.

6911. On only one occasion?—It at once attracted the attention of the mother, an extremely careful and very intelligent woman, who forthwith went to the milkman to ask him straight.

6912. And he said that he had supplied them with non-boracised milk up to when?—Up to that very day.

6913. Have you had any experience of the use of sulphite of sodium as a preservative in meat?—We have had some; I have heard of the use of it.

6914. It is used in America a good deal?—I have not made definite inquiry into it.

6915. Do you know anything of the preservatives in fish; have you had any experience as to that?—Fish was at one time experimentally preserved some years ago, I remember well, with boracic acid, but it was given up.

6916. Why?—Because it destroyed the flavour of the fish. Certain members of the fish trade were interested in it at the time. It was thought to be a new thing which was going to preserve fish better than salt, and it interested me too. I tried the fish preserved in this way several times, but it was not good. If I remember rightly it quite destroyed the flavour. I am not aware that the extensive use of that preservative has been returned to.

6917. Have you heard of the preservation of fish by formalin?—Yes.

6918. Do you know if that is carried on at all?—That I have no definite information about.

6919. Have you ever heard of the use of boracic acid for keeping oysters fresh?—No.

6920. There is a case which I have been reading in an American Committee's report where thirty-eight grains of boracic acid were found in a pound of oysters; would you see any objection to that as prescribed to invalids?—Those, of course, were tinned oysters, I presume?

6921. No; I think it was simply added to keep the oysters apparently fresh?—I should object to that most strongly. I should be very sorry to eat the oysters.

6922. As regards the behaviour of infantile diarrhoea in Liverpool, is there nothing which you can give us any information upon from the point of view of the preservatives used?—I am afraid not. There is no doubt about this, that the infantile diarrhoea which is so prevalent and fatal in Liverpool is owing to the use of feeding bottles containing putrefactive and putrefying matter. I do not think that any remedy could be looked for in adding preservatives to the milk which is put into those feeding bottles. Simply you would be just where you were. You would get the boracic acid doing the mischief that the organisms are doing—possibly in a different way, but the results of experimental investigation upon animals leads one to conclude it would be exactly the same.

6923. In reference to salicylic acid, I gather that as much

as 150 grains of salicylic acid have been found in a gallon of wine?—Yes.

6924. That is about nineteen grains to the pint?—Yes.

6925. Do you regard that as a danger to the public health?—I think it would be one of the things which would upset the children to whom that stuff is given at children's parties and so on.

6926. What wines are you more particularly speaking of here?—Orange wine; what they call British wines, made from fruits of different kinds.

6927. How much of this sort of wine do you think would be consumed by an individual in a day or at a sitting?—Very little.

6928. So you would hardly think that a very serious matter in these instances?—I do not think it is a serious matter, but I think it is objectionable and unnecessary. One finds a very much smaller amount in some than in other samples of the same thing, and one can see no reason why such a lot should be put in. Black currant wine is another of the British wines.

6929. Have you any evidence as regards the use of copper as a colouring matter that you would like to state

to the Committee?—Copper is not an uncommon thing in peas, and in the bottled fruits that one sees—beans and so on, fresh, green-looking things. There the question again comes to be one of quantity to a very great extent. Our prosecutions for the use of that colouring matter, copper, have been undertaken where the quantities seemed according even to the evidence of the trade to be excessive and unnecessary— $2\frac{1}{2}$  grains to a pound, say. The trade do bring forward evidence to show that a small quantity, half a grain to a pound, is necessary to give a fresh colour to the peas. We have not undertaken prosecutions where so small an amount as that has been present.

6930. Do you think it is established that copper in the form in which it exists in peas is soluble in the human economy?—I think it is.

6931. Would you mention the experiments you would base that conclusion upon?—I base it upon what has been told me, what I have been informed by persons who have taken these peas. One very eminent professor of chemistry has expressed himself very definitely upon his own personal feelings in the matter.

6932. Did he have symptoms of copper poisoning?—He had great uneasiness and indigestion resulting from the use of coppered peas.

Dr. E. Hope,

7 May 1900.

Dr. E. H. STARLING, called; and Examined.

Dr. E. H.  
Starling.

6933. (Professor Thorpe.) You are a Fellow of the Royal College of Physicians and a Fellow of the Royal Society?—Yes.

6934. You have been deputed to attend here on behalf of the College of Surgeons to give evidence at this inquiry?—Yes.

6935. What have you to say of your own personal knowledge as to the behaviour of the various preservatives; in the first place you had better tell us what are the preservatives which in your opinion are most constantly employed?—On that point I have no experience whatever, and I have no special knowledge.

6936. You do not know what preservatives are actually used?—Only from hearsay.

6937. What are you led to believe they are?—Formalin, salicylic acid, boracic acid, and borax.

6938. Have you made any experiments as to the behaviour of those things?—I have made certain experiments with regard to the action of formalin, not especially with regard to this practical point, but in the laboratory I have made experiments from a physiological point of view on the action of formalin and the action of salicylic acid on the digestive juices and their digestive power on foods.

6939. Will you kindly state the result of your observations?—With regard, in the first place, to formalin, I have found that proteid substances, that is to say, meat substances and fibrin, treated with only very small quantities of formalin—1 in 1,000—become practically indigestible. A shred of fibrin which would be digested by the action of the gastric juice in five or ten minutes is intact, or practically intact, after two days. This action of formalin on fibrin is not removed by continued washing with water. I have washed it in running water for two or three days, and the fibrin still remains indigestible. In the same way I have experimented, using formalin to prevent decomposition in the artificial pancreatic juice, the other chief digestive juice of the body. There, of course, it prevents decomposition extremely satisfactorily, but it absolutely stops all digestion; so that I should say the use of formalin prevents any foods, at any rate, of the nature of proteids—that is to say, meat foods—from being digested, and takes away their food character altogether.

6940. For that reason do you think its use in food supplies ought to be prohibited?—Formalin certainly should be absolutely prohibited.

6941. What have you to tell us as regards salicylic acid?—Salicylic acid is certainly less harmful. In an acid medium, that is to say, the medium in which the stomach digestion goes on, it acts as an antiseptic, but in the stomach where it is acting as an antiseptic it also prevents the action of the gastric juice, and stops digestion in the stomach. Clinically, of course, one knows that the use of salicylic acid, especially in the free state, is apt to cause symptoms of gastric dyspepsia, pain in the stomach, and stoppage of gastric digestion. In an alkaline medium it apparently is not an antiseptic at all—that is to say, when the food gets down to the intestines where the medium is alkaline, and where it is attacked by the pancreatic juice,

it does not disturb the digestion, and there, of course, it is not acting as an antiseptic.

6942. Then what is your view as to the legalisation or otherwise of salicylic acid?—Salicylic acid is a drug, and a fairly potent drug, extremely potent in certain individuals; I do not think it ought to be given except as a medical remedy. I certainly do not think it ought to be used unknown in food stuffs.

6943. Would you allow its use, therefore, if it was indicated that it was present?—For myself I should feel inclined to forbid its use entirely.

6944. Now turning to boracic acid and borax, what have you to tell us?—There one has certainly the least harmful of those three antiseptics. Experiments on animals have led to very little results, that is to say, with very large doses of borax given with the food vomiting is produced, but with ordinary doses of boracic acid and small doses of borax—such as is generally contained in food kept sweet by them—dogs, for instance, take the food and are apparently unaffected by it—all their processes are unaffected by it, they put on fat and so on. Of course, borax and boracic acid are absolutely foreign to the animal body, and its innocuous character seems to be due to the fact that it is rapidly eliminated from the body and passes off through the kidneys. So that from the point of view of an experiment carried out on a healthy animal during a few days or a few weeks one cannot say much against boracic acid or borax. Of course, on the medical evidence (of which my knowledge is only second-hand or dates from some years back when I had to do with cases), I should object to the use of boracic acid and borax from its action, especially in milk. Medical literature is full of cases of dyspepsia and cases of dryness of the skin, dryness of the mouth and certain skin affections which are said to be produced by boracic acid, or by the use of borax. Of course, in many of those cases the presence of borax or boracic acid was rather assumed than proved by chemical investigation. Much of this evidence is mere hearsay evidence, but I think there is so much of it, that there is probably some truth in it. I have known of one or two cases in which the milk was analysed and in which symptoms of dyspepsia in an infant were certainly due to the presence of boracic acid in the milk.

6945. Is infantile scurvy ever likely to be produced by boracic acid or borax?—That term scurvy is very largely a question of malnutrition. It might be produced by the presence of borax just as by the taking of infected milk.

6946. Do you think infantile scurvy is likely to be produced by the use of sterilised milk, sterilised in the ordinary way?—I think it is extremely unlikely. There are one or two medical men who have laid a good deal of stress on the production of scurvy by sterilised milk. They say that boiling the milk or heating it destroys some mystic property that it has, something connected with its living characters or something of that sort, or perhaps some ferment which is essential to the life of the young animal. There is no doubt that there are certain minute properties in milk—anti-toxic properties—which are derived from the mother, and which are an inherited gain

Dr. E. H.  
Starling.

7 May 1900.

for the infant, but which are not absolutely necessary for the infant. I think an occurrence of scurvy, that is to say, of malnutrition, as the result of sterilised milk is extremely unlikely, and at any rate it is extremely uncommon. The number of houses in which children take nothing but sterilised milk during the whole of their younger existence is very large indeed, and I have never come across a case of infantile scurvy which could be said to be produced by sterilised milk. The anti-toxic properties of cows' milk would probably be of no advantage to the human infant, and their destruction by boiling would be therefore a matter of no importance.

6947. Is infantile scurvy more prevalent in certain sections of society than in others?—That again is a statement that has been made.

6948. In what particular section is it most prevalent?—In the higher classes.

6949. It would be the higher classes that would probably use sterilised milk to a greater extent?—Yes.

6950. And the two things have been connected together as cause and effect?—Yes.

6951. Is that the only connection which has been traced?—That is all, I think.

6952. Is it upon that supposed connection that the inference is drawn?—I think so; simply that the children were fed on sterilised milk and that they got scurvy, and therefore since there was no infection it must be due to the sterilised milk.

6953. But no direct experiments have been made to show that?—No direct experiments at all.

6954. What is your view as to the legalising or otherwise of boracic acid and borax in milk; would you tolerate its use?—I should not tolerate its use.

6955. If it can be shown to you that it would be perfectly possible to carry on a milk supply without the use of preservatives, you see no reason why they should be allowed?—No, I certainly think they ought to be forbidden. Supposing its use is allowed, one might be taking borax, this foreign constituent, the whole of our lives, and excreting it through our kidney cells, and I should think it extremely unlikely that the kidneys could go on excreting this foreign substance for years without suffering from it. It is a foreign substance which affects life, which affects protoplasm, to which the antiseptic action is due, and I should think it is extremely unlikely one could go on taking it for years without suffering from it.

6956. Do you think, as regards children, it is an unnatural labour to throw upon the kidneys to expect them to excrete this substance?—As regards children the ill effect is shown earlier in the alimentary canal. The child's stomach cannot stand the presence of borax and boracic acid, and so we get the symptoms of vomiting and diarrhoea which are at once checked by changing the milk. In some cases I have known improvement follow getting milk from a farm near at hand instead of getting boracised milk from a distance.

6957. (Dr. Bulstrode.) With regard to formalin, are you familiar with the experiments of Drs. Rideal and Foulerton?—Is that with regard to the administration of formalin.

6958. With regard to the effect of formalin upon the animal tissues, and with regard to its effect upon nutrition?—I do not know that. I am not familiar with those experiments. I have seen some experiments in which formalin was given without very ill results.

6959. But you are not familiar with that paper?—No, I do not think I am; I do not remember reading it.

6960. Your conclusions as regards the effects of formalin are drawn from your own experiments alone?—From my own experiments.

6961. Have you published those experiments?—No, I have not published them. I was not dealing with the effect of formalin, I wanted to use formalin as an antiseptic. It would be a great convenience to me to be able to use formalin as a preservative for various kinds of foods.

6962. You were using it in the strength of one in 2,000?—Yes.

6963. Have you tried any experiments with much weaker proportions than that?—I have tried it in the proportion of 1 in 10,000 to preserve material, and I have tried it in the proportion of 1 in 5,000 to keep the pancreatic digest sweet, but I found the proportion of 1 in 5,000 stop the action of the pancreatic juice.

6964. What do you find with 1 in 10,000?—I have not tried the effect of that on digestion, so I could not say; I merely found it was a sufficient antiseptic in that stage.

6965. Would you contemplate any damage to the kidneys from the use of formalin as a preservative—even dilute formalin?—Formalin has been employed as a remedial reagent in phthisis by inhalation when considerable amounts have been taken in, and so far as I know no ill-effects have been observed except the disturbance of digestion.

6966. Your objection to it would be based upon the results of your experiments and its effect upon proteid matters?—Its effect upon proteid and its effects upon the digestive activity.

6967. Do you think this question of preservatives is an important one for the medical profession from the point of view of the administration of drugs?—In certain cases, yes. In the case of salicylic acid, for instance, I should think it is very important to know whether salicylic acid has been taken by the patient or not.

6968. For what reason; would you tell the Committee that?—Because salicylic acid has a definite action; it is given in large doses in rheumatism—at any rate, it is given in as large doses as the patient can stand; and we might be giving a patient too large a dose, producing sometimes a poisoning effect, when one thought one was only giving a small dose. If we give too large a dose—and the definition of that "too large" a dose varies with the individual very largely—one may produce first buzzing in the ears, then deafness, then insanity, or, rather, temporary mania—a very serious condition in which in some cases patients have committed suicide; of course, it only lasts a short time. Therefore, it would be very important to know that one was starting, so to speak, from the base line, and not in front of the base line.

6969. Are you speaking of the results of recent experience with salicylate of soda?—Yes.

6970. Is the production of delirium as common as it is used to be when rather impure salicylates of soda were used?—From my own experience I am not fit to give you an opinion on that; opinions seem to vary on that point.

6971. Would you tell the Committee under what morbid conditions you think the administration of salicylic acid or salicylate of soda would be contra-indicated?—Certainly in any case where there is any cardiac weakness or any reason to anticipate cardiac failure.

6971\* In those cases you would prescribe salicylic acid with great caution?—Yes.

6972. Therefore you would be averse to its indiscriminate use in the foods of the people?—Most certainly.

6973. Can you say under what conditions you think boracic acid is contra-indicated?—There, again, if there was any lesion or disease of intestinal tract—in typhoid, for instance—I should think it would be extremely dangerous.

6974. Do you think it would be dangerous to feed a typhoid fever patient upon milk containing 20 grains of boracic acid to the pint?—I would much rather feed him on beef steaks; I should think it would be very dangerous to feed him on that.

6975. (Professor Thorpe.) Are not large quantities of milk taken by such patients?—Three pints a day is the normal amount, and in other cases of febrile disorder, cases of diphtheria and so on, one might take as much as six or seven pints a day—we administer as much milk as the patient can take.

6976. In such cases the use of boracised milk might be injurious?—It would give rise to vomiting, and might ruin the case altogether.

6977. (Dr. Bulstrode.) Do you know anything as to the cumulative effect of boracic acid in cases where the kidneys are diseased?—No, I know nothing about it. All I know is that in healthy cases there does not seem to be a cumulative effect.

6978. Would you prescribe it in cases where you know the kidneys were diseased?—So far as I know boracic acid is not prescribed in any case except externally as an external application, and there I do not think the presence of kidney disease has been looked upon as a contra-indication.

6979. Do you know anything as to the use of sodium sulphite; do you think that would be a safe preservative to use?—Here I am not talking with much authority, but I should say that sodium sulphite would probably have very little ill-effect except as an irritant; in that case it would be in some way comparable to borax.

6980. What dose of sodium sulphite is used in medical practice, do you know?—I cannot say; I have never prescribed it.

6981. Can you tell the Committee anything with regard to the solubility of copper in peas?—The condition in which it exists, do you mean?

6982. Whether it is soluble when taken into the human system in the condition in which it exists in peas?—There I can only argue *a priori*, as I have no definite facts to go upon. I may say that copper sulphate will probably enter into combination with the proteid constituents, and that would be soluble either in dilute acid or in a dilute alkaline solution, and therefore would be absorbable. Experiments have been made with these copper albumenoids in animals, and sometimes a poisoning effect has been produced. On the other hand, of course, the action of copper is very largely on the intestines, and therefore one does not need absorption of the copper to take place.

6983. Would you be opposed to the use of small amounts of copper for colouring matter in peas?—Yes, I should, most certainly.

6984. Quite small amounts of sulphate of copper, say a grain to a pound?—Copper in a dilution of one in two millions has an appreciable effect upon living things; it is one of those substances which has a very appreciable action in very minute doses, and therefore I should think it was very dangerous, at any rate if one constantly takes in, say, half a grain to a pound of peas.

6985. Constantly?—Yes; of course, one small dose one can survive.

6986. Upon general principles, would you see any objection to the use of an antiseptic in food which inhibits the growth of micro-organisms; do you think that would affect the secreting cells of the economy?—Yes; on general principles I should say it was highly unwise to

employ any antiseptic in food, because after all there is the living stuff, the protoplasm, of the micro-organisms that cause putrefaction, and the protoplasm of our body are one and the same thing, and these general antiseptics that one gets are poisons for the whole—they are poisons for the one living material just as they are poisons for the other. One may get variations in degree which one may make use of in treatment. Thus one can get a poison which will poison some form of living organism, such as the malaria organism, more quickly than it will poison the human organism.

6987. Do you think the difference of degree might be made use of in regard to preservatives?—It would be very dangerous to make use of that, because one is always apt to get a cumulative effect; one would be having the small effect of the dose on the human organism, though one had the total destruction of a microbe which might have infected the food, but this small dose would cumulate, it would be a constant factor tending to diminish the vitality of the body.

6988. Are experiments with artificial gastric juice reliable as regards what may take place in the body?—They are reliable, but they are probably harder, so to speak, on the drug used, on the antiseptic, than experiments on the living.

6989. Harder on the drug?—Yes, because in the living animal one has organisms of defence; supposing one gives a drug into the stomach of the living animal, the stomach so far as it can removes the deleterious material so that it can proceed on its way with the digestion of the food.

6990. You would eliminate the effect of the preservative upon the gastric cells altogether, would you not?—In artificial experiments, yes.

6991. Which with regard to formalin would be an important one from your point of view?—It would be an important one.

Dr. E. H.  
Starling.

7 May 1900.

## TWENTY-FIFTH DAY.

Tuesday, 8th May, 1900.

PRESENT:

The Right Hon. Sir HERBERT MAXWELL, Bart., M.P., F.R.S. (*Chairman*).

Professor T. E. THORPE, F.R.S.  
H. TIMBRELL BULSTRODE, Esq., M.D.

F. W. TUNNICLIFFE, Esq., M.D.

CHARLES J. HUDDART, Esq., *Secretary*.

Mr. CARL W. SORENSSEN, called; and Examined.

Mr. C. W.  
Sorensen.

8 May 1900.

6992. (*Professor Thorpe*.) You are consulting expert to the Manchester Pure Milk Supply Company, Limited, I understand?—Yes.

6993. And you were formerly chief dairy expert to the New Zealand Government?—Yes.

6994. Over what length of time did your New Zealand experience extend?—Seven years in all, three and a half years of which I spent as manufacturer and shipper of dairy produce on my own account, and three and a half years with the New Zealand Government.

6995. Your first knowledge of preservatives I believe was when you used them experimentally on the advice of your London agents in a few tons of butter?—Yes, that is so.

6996. What was your experience in regard to that experiment?—My experience was that nothing was gained from a commercial point of view. Theoretically it was claimed that there was some slight gain, but it did not affect the price of the butter in any way. I got not a penny more for the butter treated with preservatives than I did for that without.

6997. When you say that theoretically it was claimed that something was gained, what do you mean by that?—I mean that the agents reported that one or two boxes were particularly fine, but they could not get any more money than for the average.

6998. Would that assume that there was a distinct improvement in those particular cases owing to the use of preservatives?—No, I think not.

6999. As the result of that experiment, however, you did not think fit to continue the use of them?—No, I saw nothing to be gained by it, and as the use of preservatives entailed a considerable expense I gave it up.

7000. Were your London agents satisfied?—Quite.

7001. When you became appointed as chief government expert you found, I understand, that opinion was divided as to the value of the use of preservatives?—Yes.

7002. Would you kindly state to us what you observed?—I observed the fact that large factories were using preservatives and claiming that they got considerable benefit, whereas others equally large were not using them, and found their results quite as satisfactory. I accordingly instituted a series of inquiries amongst the factories, sending out circulars with a list of questions to be answered by owners and managers. The verdict was that 60 per cent. found the preservatives unnecessary or useless, 20 per cent. were undecided or declined to express any opinion, while the remaining 20 per cent. were in favour of their moderate use.

7003. Were the 20 per cent. who were in favour of their moderate use large or small exporters?—Some of them were very large; indeed some of them were the largest exporters in the colony.

7004. Those people found it desirable to use them?—

Mr. C. W.  
Sorensen.

8 May 1900.

Yes—to a very small extent, however—to the extent of one quarter per cent.

7005. They resolved themselves into not more than about that?—One-fourth to one-half at the very outside.

7006. Are we to assume then that the greater portion of the butter which comes over to this country from New Zealand contains preservatives?—At the time when I left New Zealand I could safely say that two-thirds of the butter was not treated with preservatives.

7007. Two-thirds of the butter which reached these shores was not treated with preservatives?—Yes.

7008. How does the matter stand now?—I am not able to express any opinion as to how it stands now.

7009. Do you imagine that the use of preservatives is gaining further favour?—I have some further reason to think that there has been an increase in their use since I left.

7010. How do you imagine that increase has been brought about? Has pressure been brought to bear upon them; if so, from whom—from here or how?—In one or two cases it has, but not so much so perhaps as formerly. I can remember about five years ago when certain London firms importing butter from New Zealand stipulated that the butter should be treated with a certain percentage of boracic acid or other preservatives, but on the other hand these preservatives had to be obtained from these particular firms or their agents. Lately I think that custom has rather died out. Pressure has no doubt been brought to bear in other ways. My successor as chief dairy expert has not been altogether opposed to them I understand—and is perhaps a little in favour of them.

7011. If certain firms stipulated that they should be put in because they themselves sold those preservatives, I suppose indirectly they would have to pay for those preservatives, or at all events the public eventually would have to pay for them?—Yes; but those firms simply sell butter on consignment; those firms that I was thinking of had simply the butter consigned to them, and they sold it on commission.

7012. Sold it as they could?—Yes, on commission.

7013. I understand that whilst you were in New Zealand you made directly some experiments in your position as chief dairy expert to assure yourself whether any gain was or was not obtainable by the use of preservatives, did you not?—Yes.

7014. Would you kindly tell us the results of those experiments?—The result was that we found on a number of boxes of butter made exactly alike, churned at the same time, and from the same cream—the butter that was treated with preservatives kept slightly better than that without; but the gain was a very slight one. I think the points were a maximum of 45 for flavour; the butter treated with preservatives scored at the end of eleven weeks 37 points for flavour in one case, and 36 in another, or an average of 36½; and the butter that was not treated with preservatives scored 32 to 34, showing a slight gain for the chemically-treated butter.

7015. That is to say the flavour was preserved?—Yes, the flavour was preserved to a better degree.

7016. What were the amounts in which you got the most favourable result?—A half per cent. was found quite as efficacious as any larger quantity; if you exceeded that half per cent. the flavour of boracic acid was distinctly noticeable in the butter.

7017. What kind of flavour has boracic acid—do you mean a taste?—Yes, a saline taste.

7018. What was the influence of that experiment upon your own convictions?—The experiments were not sufficiently conclusive to warrant me regarding the verdict as final, and I was still unconvinced that it was necessary to use preservatives for New Zealand butter considering the practical fact that two-thirds of the butter leaving the Colony at that time were not treated with preservatives, and reaching home in as good a condition as that which was so treated. I felt, too, on higher ground that we were running a risk of imperilling our reputation for the purity of the product; I thought unless the evidence was very strong that we should not do anything to endanger that reputation.

7019. You thought in fact that because certain shippers could do without it the rest might?—Yes, the rest could.

7020. The gain, in your opinion, was so trifling that it was not worth your risking the reputation of the butter?—Exactly.

7021. Have you anything further to add with respect to butter?—No, that is all.

7022. Now, we pass on to what you have to tell us respecting milk and cream; would you kindly say what the result of your observations and experience there is?—I am intimately connected with the Copenhagen Milk Supply Company, which was started by a relative of mine some 21 years ago on philanthropic motives, with the idea of supplying the town of Copenhagen with an absolutely pure supply of milk at the lowest possible price it could be done for. Through all those years not one ounce of preservative has ever been used in any of the milk or cream, or other dairy products sold by this company, and their sales now amount to something like 15,000,000 lbs.—1,500,000 gallons.

7023. Are preservatives used at all in Denmark?—They are not used in the milk supply of towns. They are very strictly prohibited by law. The police are constantly taking samples, and I think I may say that the law is enforced.

7024. Then where are they used if used at all; you say they are not used in the milk supply of the towns?—In the smaller villages the police administration is not so strict, and preservatives may be used there. In the larger towns preservatives are not used.

7025. Why is not the law as stringent in the smaller places as it is required to be in the large towns?—I think common experience is that it is not so.

7026. But is it not the fact that the necessity, if there be a necessity, for the use of preservatives, would be more felt in the larger towns than in the smaller places?—Quite so.

7027. Then it seems odd that in a place where, if there is any gain at all in their use it is there to be found the law is very stringently set in motion, whereas in the smaller places, where the milk, so to say, is more nearly to hand, the use of preservatives is tolerated?—It is tolerated because these small villages may not have analysts and inspectors to enforce the law.

7028. Are you personally acquainted with Dr. Stein?—Yes, I was many years ago, but I have not seen him for many years.

7029. What are his functions, if he has any, with respect to the organisation which controls or checks the use of preservatives?—He is official analyst for the Government of Denmark, and for the city.

7030. Will not his jurisdiction extend over the smaller places then?—Yes, I suppose if the outside bodies were to send in samples, I am not prepared to say but what he would analyse them.

7031. Then it is not the absence of a local analyst which causes the law to be slackly enforced; it is rather the slackness of the authorities themselves?—I presume so.

7032. Your point, however, is that judging from the example of Copenhagen, it is quite possible for a large community to be supplied with milk without the use of any preservatives?—That is so, and the experiment has lately been tried in this country as well.

7033. Where?—In Manchester; I will not say that there are not other milk supply companies that deliver milk without any preservatives, but I can at all events vouch for the Manchester Company to which I am consulting expert.

7034. Are you aware of any other continental cities that carry on their milk trade without the use of preservatives?—I cannot speak authoritatively on the point. One point in the Copenhagen system that I would like to bring out is that there is only one delivery of milk per day as against the two deliveries universally practised in this country.

7035. What advantages has that system over the method here?—The advantages are, a reduction in the cost of delivery there, so enabling you to spend more money on getting pure milk from healthy cows; and in enforcing precautions as to cleanliness both on the farms and in the course of distribution without enhancing the cost of the milk to the consumer.

7036. How is that secured otherwise?—How can you secure in Manchester, or in Copenhagen, one delivery per day?—Simply through cleanliness and the strict, prompt cooling of the milk immediately that it is milked.

7037. The prompt cooling of the milk would be, of course, relatively speaking, a costly procedure, would it not?—Relatively it is; to be properly cooled it must be cooled with ice.

7038. Ice in this country is not so easily obtainable as

it is in Denmark, is it?—It is perhaps more easily obtainable than is generally thought. For instance, this last winter all our farmers have succeeded in obtaining a supply of natural ice or snow, to be used during the coming summer. It is stored under peat moss or sawdust, or other insulating material, and is taken out from day to day as required. There is very little expense about it, and I may say that it can be done for about 2s. 6d. to 5s. per ton.

7039. Do you think the climatic conditions of this country are so constant that we could ensure in that way year after year a natural supply of snow or ice?—In nine years out of 10, I believe that it is possible to do so. Shortly after I came over here I consulted a Manchester gentleman, who has been in the habit of collecting ice, and snow for the last 40 or 50 years. His experience is that only perhaps four or five times during that period has he not been able to get a supply of natural ice or snow.

7040. That would necessitate, of course, that every farmer had an ice-house or some similar contrivance?—Not necessarily.

7041. How do you preserve the ice?—Simply stack it in the open as you would potatoes or turnips, and cover it up with sawdust or peat moss about two feet thick all round.

7042. Is that the way in which it is actually done by the farmers in connection with the Manchester Supply Association?—Yes.

7043. Then your point is that if the milk is sufficiently refrigerated no matter whether it be delivered once or twice a day, it would be still possible to deliver it without the use of any preservatives?—Without any preservatives whatever.

7044. But you think that if a daily delivery only could be arranged it would more than compensate itself for the cost of refrigeration?—That is our experience.

7045. And that thereby you could indeed deliver the milk somewhat cheaper than at present it is delivered?—Yes, other things being equal.

7046. Would that not rather tend to concentrate the milk supply into comparatively few hands?—Undoubtedly it would, and I think it would be a distinct gain to the community that it should be so.

7047. In the first place, it would rather tend to the concentration of the milk supply in the hands of the farmer, as well as in the hands of the vendor, would it not; I mean small farmers would not have the appliances, and could not undertake the additional cost of freezing the milk, could they?—I think so. We have suppliers who are both in a very large way, and in a very small way; I mean to say that they range from 12 or 15 cows up to 200.

7048. How many farms are worked in conjunction with your Milk Supply Association at Manchester?—There are nine at present.

7049. What is the total volume of milk you handle per day?—I would rather not answer that question; I am not authorised to give any detail as to the actual volume of the trade.

7050. How long has it been in operation?—About 12 months this month.

7051. Of course one delivery per day would no doubt have the advantage, I suppose, that the character of the milk would be more uniform; I mean so far as its quality went?—Yes; both the morning's milk and the evening's milk being mixed.

7052. We should get over the difficulty of the disparity in the richness of the fat between the morning and evening milk?—Yes.

7053. Is it your contention that a system of one daily delivery would suit the exigencies of a place like London?—I am not sufficiently acquainted with London to be able to say; but if it can be done in Manchester I do not see why it should not be done in London.

7054. Manchester, I suppose, is mainly supplied from Cheshire, is it not?—From Cheshire and Derbyshire.

7055. That is to say its gathering ground is comparatively close at hand?—Yes, it is comparatively close.

7056. What is the longest distance the milk has to travel to you from your farms?—About a four hours' journey from the farm to our dépôt.

7057. Perhaps you are aware that milk coming to London travels sometimes a couple of hundred miles?—Yes.

7058. But that is not a condition of things which obtains in Manchester?—No, it does not with us, but there is no reason why it should not. If the milk is sufficiently cooled it will stand a journey of 200 miles just as well as it will one of 50 miles.

7059. Have you anything more to tell us with respect to your experience with the Manchester Pure Milk Supply Company?—I would simply say this: that though there was a great deal of prejudice against the single delivery when we first started, that prejudice is being rapidly overcome, and people are finding now that the milk will keep perfectly sweet in the hottest weather, and they rather prefer the single delivery, as it involves less trouble; the servants, for instance, have not to answer the bell twice.

7060. Do you mind telling us what is the nature of your contracts with the farmers, as to the character of the milk which they should supply to you?—The contracts are very stringent. I have not got a copy with me, but I can give you the essential outline. All the cows are tested with tuberculin every six months by our own veterinary surgeon, who is also the chief veterinary surgeon to the Cheshire County Council. They are examined clinically once a month as well. We have very strict feeding regulations. We do not allow any stalk feeding in the summer, and in winter we regulate both the quality and the quantity of the food to be employed. We are very strict as to the cleanliness both of the shippings and of the utensils. We supply all the milk cans used by the farmers, and undertake the cleansing of them before they are returned.

7061. Do you stipulate as to the character of the water supply?—Yes, that is a very important point.

7062. Is that examined by you?—Yes, we examine it before we take on any farm.

7063. As to the adequacy of the supply of water?—Yes.

7064. Apart from its purity, I mean?—The cooling arrangements, of course, are very strictly looked into. We insist on every farmer cooling the milk to 40 degrees as soon as ever it is milked. If he cannot get ice naturally we undertake to supply him with it at a very low price, and, of course, we pay him a commensurate price for all this extra care and trouble that he has to take. We find that owing to the single daily delivery we can afford to do that, and yet retail the milk at a lower price than the average surrounding dairymen.

7065. Do you stipulate for a definite amount of fat in the milk?—Yes.

7066. What do you stipulate for?—Three per cent. is our limit.

7067. Do you pay him any more if he gives you any more fat in the milk?—No.

7068. What do you do if he gives you less?—We have never had such a case happen.

7069. Are you able to tell us what, as a rule, they do give you?—Yes; the average is 3·5. We take very careful tests. Every can of milk that has ever come into the dairy is tested every day—every separate can we sample and test. We have a complete record from the day of starting.

7070. What is your average; can you tell us the average amount of fat in these milks?—I could not tell you to a second decimal point, but it is either 3·5 or 3·6.

7071. When does it fall lowest?—It varies very considerably. Some farmers, we find, fall to their lowest in August, when the grass is very scarce. We have had it as low in that month as 2·7 for a single day. Of course, that is not the average for a week or a month.

7072. Do you make any stipulation as to the periods of calving—how the man should distribute them over the year—or do you leave that to him?—We insist that the calving shall be so regulated that the maximum supplied in any month shall be not more than 50 per cent. of the minimum supplied in any month, and *vice versa*.

7073. Does it happen then that the farmers with whom you deal are practically calving all through the year?—They are calving all the year round.

7074. You have had no difficulty in getting men to comply with those regulations, have you?—We had to visit a very large number of farms in the first instance to select a few, but now as we find the business increasing we have no difficulty in picking out one from time to time.

7075. The farmers are willing to conform to those regulations, are they?—Yes, very willing. They get such a

Mr. C. W.  
Sorensen.

8 May 1900.

Mr. C. W.  
Sorensen.

8 May 1900.

very high price for their milk that they would be ready to conform to rather more than we ask them, I think.

7076. Are the churns which are sent out always locked churns?—They are sealed with lead seals.

7077. Where do you take delivery of those churns?—At the railway station at Old Trafford.

7078. At the receiving end?—Yes.

7079. Up to that point the farmers are responsible?—Yes. Every farmer has his name stamped on the seal, and we examine the seals as they arrive at the dairy to see that they are intact.

7080. Does your company deal in separated milk?—Yes.

7081. Do you supply separated milk separately?—Yes.

7082. Is there a demand for separated milk by the consumer?—Yes, there is a slight demand, perhaps in the proportion of 5 or 6 per cent. of the whole milk.

7083. I suppose in the ordinary case of milk, the usual run of milk sophistication is the addition of separated milk, is it not?—There are a good many other things too—there is annatto, for instance. I think it is almost impossible to get a glass of milk in London that is not more or less coloured with annatto.

7084. That is not a sophistication of the same order as the abstraction of fat, is it?—No.

7085. The abstraction of fat, I suppose, is the most general form of adulteration, is it not?—I should say so.

7086. May I just take advantage of your being here to ask you another question relative to that. Do you not think it would be to the general interests of the community and of the honest and legitimate trader that some steps should be taken to ear-mark, so to say, separated milk?—To ear-mark separated milk?

7087. I mean to say, should something be done with it so that its identity as separated milk should be preserved all along the line?—Beyond selling it as separated milk and labelling the can "Separated Milk." I do not see what more can be done. Have you anything in your mind such as colouring it a particular colour?

7088. Something in principle like that. Do you know the principle of the German margarine law, for example?—I do not know that I do.

7089. German margarine is ear-marked by a certain quantity of sesame oil. Are you aware of that?—I did not know of that.

7090. The German Government, with a view of checking the surreptitious addition of margarine to butter, has required all margarine manufactured in Germany to be mixed with 11 per cent. of sesame oil, which in no way detracts from its quality, but allows of its ready identification, sesame oil not being, of course, a natural constituent of butter. Do you not think it would be a desirable thing to issue some regulation such as that separated milk should be mixed with something which would stamp it as separated milk, but yet in no way destroy whatever alimentary quality it had, nor do anything whatever to make it useless as food, but at the same time which would indicate actually what it was or allow an analyst to be able to detect the presence of separated milk?—I do not think it requires an analyst to detect separated milk.

7091. For example, if you took the milk of a Jersey cow containing 5 or 6 per cent. of butter fat, you could add a very large proportion of separated milk to that, could you not?—Undoubtedly.

7092. Who would tell you that you had made the addition?—In that case no one; I see what you mean, but I do not see how any law that you could frame would prevent the addition of separated milk before it had been so treated with this specific.

7093. It is the fact, is it not, that the evening milk is almost invariably richer than the morning milk?—Only, I think, when there is a difference in the period between the milkings.

7094. But there is always that difference more or less, is there not?—In practice, yes.

7095. You may have the difference as much as 8 and 16 hours, may you not?—Yes.

7096. The effect of that would mean a very considerable disparity in the amount of fat?—Yes.

7097. There is nothing at present, therefore, to prevent a man taking advantage of that circumstance and diluting his evening milk down to the standard of the morning milk with separated milk?—Nothing whatever.

7098. The general effect of that would be to depreciate the general average of the milk supply, would it not?—Quite so.

7099. Which is, perhaps, a desirable thing to check, is it not?—Yes, but I do not see how it can be checked by any legal remedy.

7100. At present perhaps not, but still, would it not be a desirable thing so to arrange that the separated milk should be ear-marked with something or another to prevent the addition of it in the manner I have indicated?—I am afraid that the only conceivable way to do that would be for the separator itself to impart some peculiarity to the milk on its passage through the machine.

7101. We might, however, arrange—might we not possibly—at all events, this is a conceivable idea—to cause something to be added to the separated milk which would at once stamp it as separated milk?—Yes.

7102. For example, as a suggestion, we might add a certain quantity of starch?—Yes.

7103. Some easily recognisable starch or a character of starch which is not likely to be accidentally introduced into it on a farm?—Yes.

7104. For example, rice starch, a very small quantity of that would be a sufficient diagnostic, would it not?—Yes.

7105. And the evidence of the rice starch could be very easily picked up analytically?—Yes; but how are you going to enforce anybody to put the rice starch into the milk?

7106. The German Government can enforce sesame oil being put into the margarine?—At a certain stage before it goes on to the market?

7107. At any stage you please that it is necessary or desirable to do it; and the Government of this country can force people to add a certain quantity of wood naphtha to alcohol to denature it?—I fail utterly to see how you can legislate to prevent a man adding separated milk to his whole milk before it leaves his own dairy, before it goes out on to the market at all if he runs his separator simultaneously with the milking.

7108. The exact details of how it is to be done perhaps we need not thresh out here; it is quite conceivable that by a system of inspection at the points of delivery and at the points of receiving by public officials this practice of the surreptitious use of separated milk might be stopped by the method I have indicated; that is conceivably possible—anyhow, what I should like to get from you without going into the question of how it is to be done is, is it abstractedly desirable to do it?—I do not know that it is without further thought.

7109. But you have admitted that fraud can go on?—Undoubtedly.

7110. And you think it does go on?—Yes.

7111. Yet cannot you bring yourself to say it is desirable to stop a fraud?—Certainly it is.

7112. That is all I want to know. You think it is abstractedly desirable to stop it?—To stop fraud. Yes.

7113. To stop this fraud?—Yes, to stop that fraud.

7114. Now it has been urged, has it not, that the prohibition of the use of preservatives in milk would enhance the cost of the milk to the public?—Yes.

7115. Are you of opinion that it would?—I think I have shown that it need not be so, and in Copenhagen the retail price of milk is 2½d. per quart for a milk very much superior to anything one can get in this country as a rule for the higher price, and in Manchester we have not found it necessary to raise the price above 3½d. per quart, while many dairymen in Manchester charge 4d.

7116. Have you told us all that you wish to say respecting milk?—Yes, as regards milk; but there is a point to be considered as regards cream.

7117. Now what have you to tell us about cream?—Very much the same as with regard to milk—namely, that there is no necessity for cream to be chemically treated any more than there is for milk if it is managed on proper lines. At present the cream trade, in Manchester at all events, goes on through grocers, fishmongers, and men of that sort, who take in cream perhaps once a week or once a fortnight, and sell what they can, and have the balance taken back. To enable the cream to keep for that week or fortnight, of course, it must be treated with some preservative, but I question whether there is the slightest necessity for it to keep that week or fortnight if the trade is diverted into proper channels. If it is delivered once a day along with the milk I do not see any

necessity for requiring it to keep for a week or a fortnight.

7118. Then your point is that, because the grocers have sought to capture a portion of the cream trade, at all events, they require the use of preservatives?—Exactly.

7119. But that if the sale of cream were confined, as hitherto, to persons strictly in the dairy trade?—To any one who would deliver it fresh once a day—

7120. There would be no necessity for the use of preservatives?—None whatever. In Copenhagen they retail as much as two tons of cream per day in glass bottles, and they never use any preservative whatever.

7121. In Copenhagen it can be as hot as here, can it not?—Yes, fully; hotter in summer.

7122. The extremes of temperature are much greater there than they are here?—Yes.

7123. Has the cream of Copenhagen any long distance to travel before it reaches the city?—It has practically the same as the milk; it comes by rail from farms three or four or five hours away.

7124. Have you anything more to tell us about the cream?—I think not.

7125. (*Dr. Bulstrode.*) You say that 1 per cent. of boracic acid gives rise to a boracic acid taste?—Yes.

7126. (*Dr. Tunncliffe.*) In butter that is, is it not?—Yes

7127. (*Dr. Bulstrode.*) Do you know that the agent-general of the Colonies in communicating with Mr. Chamberlain in reference to this subject stated that they had been advised that 1 per cent. would be perfectly innocuous:—They say, "But our main object in approaching you is to request you to be so good as to bring the matter before the President of the Local Government Board with a view to the exact amount of boracic acid which may be used in preserving butter being authoritatively defined." In making that statement do you think they had regard to the fact that 1 per cent. gives rise to a taste?—Was that from New Zealand?

7128. From all the Colonies—Victoria, New South Wales, Queensland, South Australia, Tasmania, and New Zealand?—I can only say that that is our experience, that 1 per cent. does give a taste to the butter—a distinctly noticeable taste.

7129. You said you could not tell us as to the conditions that obtained in New Zealand in reference to the use of preservatives in butter at the present time?—No, I cannot.

7130. You stated that you were unwilling to tell the Committee the extent of the trade of your company in Manchester; would you mind stating, if you feel you can, whether the trade is promising?—Undoubtedly.

7131. You can state that without a doubt?—Yes, I can state that the trade has doubled within the last six months.

7132. And you say that it is necessary in order that you may have a delivery once a day to procure ice?—Yes, absolutely necessary.

7133. Would you say that ice is necessary if you have a delivery twice a day?—No, I should say not.

7134. So that really with the methods of delivery which we have now, we may get on without the use of ice?—Quite so.

7135. By simply cooling with cold water?—Yes.

7136. In making your statement, which was based, I think, on the opinion of a Manchester gentleman, was it not, as to the procuring of ice and snow for nine years out of ten?—Yes.

7137. Had you regard to the fact that Manchester is considerably more north, say, than Brighton, and that in Brighton and elsewhere on the south coast there might be some difficulty in procuring ice?—That is so.

7138. Do you think the average of nine out of ten would obtain further south—in the Isle of Wight, for example?—I am not sufficiently acquainted with the south to have any opinion on that.

7139. Do you think cooling to 40 degrees only is necessary to ensure a delivery once daily?—Yes.

7140. But you would cool to a smaller extent for twice a day?—Yes.

7141. In cream you say in your *précis* you have found as much as 157·8 grains of boracic acid per gallon?—Yes.

7142. "Out of eight samples of cream," you say, "pur-

chased casually in Manchester in February, all of which were found to contain preservatives, four, or 50 per cent., contained from 144·7 to 157·8 grains per gallon"; do you think that is a usual practice?—I think it is almost invariable. 8 May 1900.

Mr. C. W. Sorensen.

7143. And in that amount?—In those approximate amounts.

7144. You think those are fair average amounts?—Yes; these samples were taken in February, when the weather is distinctly cool.

7145. You have got no figures of samples taken in August, have you?—No.

7146. (*Dr. Tunncliffe.*) When you say that 1 per cent. of boracic acid tastes in butter, do you mean that it tastes *per se*, or that it alters the taste of the butter in a certain way?—One notices a peculiar flavour in the butter.

7147. What do you think that is?—One is at a loss to attribute it to anything but the preservative.

7148. But if you did not know the boracic acid were in the butter you could not recognise the boracic acid as such, could you?—No, one might not.

7149. It might be any other preservative, for instance?—Quite so.

7150. Then what it amounts to is that it alters the taste of the butter?—Yes, it imparts a taste to the butter.

7151. I should like you to tell the Committee, if you can, something with regard to the social standing of your *clientèle* in Manchester; are they amongst the better classes?—They are very mixed—both amongst the better and the poorer classes.

7152. And the majority is amongst which class?—The middle class.

7153. In short, amongst the people who have fairly good domestic appliances for keeping milk?—Yes, quite so—not amongst the very poorest, because the very poorest are supplied in Manchester with milk at 2½d. per quart—such as it is.

7154. Do you know anything about the hygienic conditions of the poor classes in the large towns of England?—Not more than an ordinary individual does.

7155. How do you think they would compare with regard to space and appliances for keeping milk with the conditions of the lower classes in Copenhagen, for instance?—I do not think they would compare altogether favourably.

7156. Do you think that the poor people in Copenhagen would have a better chance of keeping their milk domestically than the poor people of London?—I should say so.

7157. You supply direct to your customers, and you have no dealings with middlemen whatever, I understand?—No, none whatever.

7158. I understood you to say that the fact that you delivered milk only once a day enabled you to keep the price of milk down in spite of the somewhat more elaborate *technique* which you use?—Quite so.

7159. So therefore if milk had to be delivered twice a day you would not be able to do it at the same price?—Yes, we should, because one would not need to use ice in that case.

7160. You think those two conditions would balance each other?—I think so.\*

7161. Did you make any experiments with any more than 1 per cent. of boracic acid?—No, that was the maximum amount used.

7162. Speaking roughly, would a higher percentage, do you think, have a better preservative action than one per cent.; do you think, for instance, if you put 2 per cent. in it would keep the butter longer?—If there is any

\* I would like to correct this; if I really did make this statement it must have been under a misapprehension. As I stated in Qs. 7033 and 7158 it is distinctly owing to the economies effected in having only *one* daily delivery that we can pay an extra high price to our farmers for a perfect milk, and yet retail the same to the public without raising the price above the average. If we had to give two daily deliveries we should have either to charge more or forego some of our precautionary measures. My point is that, if we can do without preservatives while delivering only *once* a day, those who deliver *twice*, even without using ice, can also do without them. I wish to correct my statement that the saving in ice will balance the additional expense of a second delivery.—C.W.S.

Mr. C. W.  
Sorensen.  
8 May 1900.

preservative action in it, I should say that it would, but then you have the question of taste; you would make the butter altogether useless from the taste point of view.

7163. Two per cent. would make it quite useless, you think, from the taste point of view?—I should think so.

7164. Are there any special precautions with regard to the transit of milk and butter in New Zealand?—The Government supply refrigerator railway cars on their own lines for butter, and the steamship companies that run to meet the mail steamers also supply insulated space.

7165. Are there any such appliances in Denmark?—For butter?

7166. And for milk?—Yes.

7167. For both?—For milk the Copenhagen Company has its own railway vans, which it keeps supplied with ice itself.

7168. And for butter?—For butter, I think the Government provide refrigerator cars.

7169. But you have no such appliances in Manchester?—None whatever.

7170. Your milk and butter are carried, so to speak, haphazard by the railway companies?—Quite so.

7171. (*Professor Thorpe*.) The greater portion of the milk supplied in Denmark is sterilised or pasteurised, is it not?—No, I should say not the greater portion.

7172. Is not the greater portion of the milk supplied to the city of Copenhagen pasteurised?—No.

7173. Is not any large proportion pasteurised?—A con-

siderable proportion is pasteurised, but I should not say it was the greater proportion.

7174. Would that not have something to do with the keeping qualities of the milk?—Undoubtedly; but none of the Copenhagen Supply Company's milk is pasteurised—none whatever.

7175. Do you contemplate the necessity of pasteurising in Manchester?—No, we are entirely opposed to the practice.

7176. Why are you opposed to it?—We are opposed to it because it is unnatural, and we believe that it is injurious to very young children or invalids who are fed on it.

7177. Why?—That is on medical advice.

7178. In what sense is it injurious?—It is less digestible.

7179. What does pasteurising the milk do to it chemically?—It caramelises the milk sugar and it coagulates the albumen.

7180. Is the temperature sufficiently high to caramelise the milk sugar?—It does; it imparts that peculiar taste.

7181. I may be wrong here, but I understand—and I have it on the authority of Mr. Faber—that properly pasteurised milk has no taint or flavour?—I am afraid I cannot agree with Mr. Faber though.

7182. You think it has?—Absolutely.

7183. Anyhow you have deliberately in Manchester decided not to sterilise or pasteurise?—Yes.

Mr. A. R.  
Anderson.

Mr. ALEXANDER RICHARD ANDERSON, called; and Examined.

7184. (*Professor Thorpe*.) You are a Fellow of the Royal College of Surgeons?—Yes.

7185. And you are surgeon to the General Hospital, Nottingham?—Yes.

7186. You have had some experience, I believe, in prescribing boracic acid?—Yes, I have.

7187. And in observing its effects?—Yes.

7188. Would you kindly tell the Committee what that experience is?—I began to prescribe boracic acid chiefly in cases of bladder trouble in the year 1892, and as I found it to do good in such cases I have continued its use since both in hospital and in private practice. When I began to prescribe it I was not aware that it caused any unpleasant or harmful symptoms, and my attention was first directed to it by the patients themselves. My experience has been chiefly among adult males, and the drug has been prescribed in doses of from 10 to 20 grains three times a day. My experience has been that after taking the medicine in these doses the majority of cases within a fortnight will begin to complain of dyspeptic symptoms. By that I mean such symptoms as pain, referred to the region of the stomach, uncomfortable sensations after eating, loss of appetite, weariness, giddiness, nausea, and in some cases actual vomiting and eruption on the skin. On discontinuing the medicine the symptoms quickly subside, and they reappear again when the administration of the drug is resumed. This has occurred so often in my practice that I am in the habit of telling the patients that the medicine will probably make them dyspeptic, and that when such symptoms occur it must be discontinued for a time until they are all right again, and then resumed. Since the 1st January this year I have prescribed boracic acid in these doses to 14 patients, and out of that number eight became so dyspeptic that I had to omit its use. The symptoms produced by boracic acid are not, as a rule, serious, and they always quickly subside when the drug is discontinued. But the dyspepsia in my experience is sufficiently pronounced to make life miserable, while it lasts, and at times it causes distinct gastritis, with repeated vomiting. That, gentlemen, therefore, has been my clinical experience of the administration of boracic acid.

7189. Does that experience lead you to recommend that the use of boracic acid in the relatively small quantities in which it is present in milk as a preservative should be prohibited?—Yes, for this reason, that I take it the average amount of milk adulteration with boracic acid is about five grains to the pint. If a healthy adult takes a small quantity of milk twice a day the amount of boracic acid in it would be of no detriment to him whatever, but if you take the case of a child two years of age the dose

for a child of that age, according to the posological table which you will find in any work on materia medica, would be  $2\frac{1}{2}$  grains three times a day—one-eighth of the other—that is—that would be equivalent in a child two years old to a dose of 20 grains three times a day for an adult man. A child consuming two pints of milk boracised to the extent of 5 grains to the pint, would be getting 10 grains of boracic acid a day, whereas the maximum dose for such a child would be  $7\frac{1}{2}$  grains. Then, again, take the case of an adult, who is ill, and who has fever, and so forth, and who is fed exclusively on milk. If he took four pints a day, he is then getting 20 grains of boracic acid per day with his milk. His stomach being already very seriously disturbed, as in a case of typhoid, where milk is the chief article, or perhaps the sole article of diet, I say, in my opinion, that would be doing him harm rather than good.

7190. When you say would do him harm rather than good, do you mean to say it would do him serious harm?—That is a very difficult question to answer, but it certainly has an irritating effect on the stomach, which, in the case of typhoid fever (speaking not as a physician, but as one practising wholly as a surgeon), I should imagine would be the very thing one wants to avoid.

7191. In the course of your experience as a practising surgeon, you have used boracic acid outwardly as an antiseptic, I suppose?—Yes; but not to any extent, because it is a very feeble antiseptic. We use stronger antiseptics when they are wanted. I use boracic acid very little. I use preparations of mercury more.

7192. You have had no experience of skin eruptions following from the use of boracic acid as an antiseptic in surgery, have you?—No, not as an antiseptic.

7193. (*Dr. Bulstrode*.) At the hospital at which you are surgeon, is it the custom to have the milk examined for preservative?—Yes.

7194. How long has that been so?—About six months.

7195. At whose suggestion, or as the result of whose experience?—At the suggestion of the Medical Committee.

7196. For what preservatives is the milk examined?—That I am not sure of, but it is done by the City Analyst, and he sends in his report to us that it is free from preservatives or otherwise, but boracic acid is within my knowledge one that he tests for.

7197. Do you regard it as an important matter to physicians and surgeons in hospitals that they should know whether their patients are taking drugs in their food, some of which they have been in the habit of prescribing?—Certainly.

7198. It may tend to stultify the position of the physician unless that is done?—Yes; there was a very marked case that gave rise to the analysis of milk in question; but I do not know quite whether this is a thing that ought to be made public, because the milkman might easily be traced, and it might reflect upon him.

7199. I think the Committee is already aware of that fact. I think one of your colleagues here pointed out to us that within his own knowledge he treated a case, I think it was in the hospital of Nottingham?—That is the case which I am referring to.

7200. (*Dr. Tunncliffe.*) It was the case of one child?—Yes.

7201. (*Dr. Bulstrode.*) That is the case you are basing your statement on?—What statement.

7202. The statement you were giving as an illustration of the danger of the indiscriminate use of these preservatives in relation to the medical practitioner?—Yes, that is one instance.

7203. Can you supply others. We have had that instance before us?—I have had no experience practically of the adulteration of food—I mean of boracic acid in food, causing harmful symptoms.

7204. Then on general principles you think it desirable that the physician should know whether or not the milk which is supplied to his patients contains drugs which he may be prescribing for them professionally?—Certainly. If my clinical experience is worth anything at all a child taking 10 grains of boracic acid a day in milk, which it may very well do, ought to be made seriously dyspeptic by it.

7205. Are there any conditions which contra-indicate the use and administration of boracic acid?—I think it would do harm in any disease associated with fever, where the stomach and intestines are already in a state of irritation, such as typhoid fever, for example.

7206. Do you think in typhoid fever that boracic acid should be administered with caution?—Boracic acid, I think should. It is contra-indicated, because it is an irritant to the mucous membrane of the stomach and the intestines too. I am convinced of that.

Dr. PHILIP SCHIDROWITZ, called; and Examined.

7216. (*Professor Thorpe.*) You are Doctor of Philosophy of the University of Berne?—Yes.

7217. You are Fellow of the Chemical Society, member of the Society of Public Analysts, of the Society of Chemical Industry, of the German Chemical Society, and you are author and joint author of various papers and treatises on chemical subjects, and you have had some years' experience as an analytical and consulting chemist?—Yes.

7218. I believe you wish to offer evidence before this Committee on the use of preservatives in beer and milk?—Yes.

7219. You have already given evidence, I believe, before the Pure Beer Committee?—Yes, before the Beer Materials Committee in 1898.

7220. That evidence included evidence on the use of preservatives in beer, did it not?—Yes, it did.

7221. The evidence, therefore, that you wish to give on beer to-day is here in the Blue Book, is it not?—Yes, it has practically all appeared with regard to beer, but not with regard to milk. That is quite apart from the other.

7222. Then under those circumstances I do not think it is necessary to take you over that evidence, as it is already in print and available to us?—No, perhaps not. (*See App. No. 34.*)

7223. Then we will turn to the question of preservatives in milk. What have you to tell us now in respect to the necessity or otherwise of using preservatives in milk?—I recently had an opportunity of making some experiments with regard to the refrigeration of milk which I think might be of interest to the Committee. I do not wish to give any evidence as to whether preservatives are harmful or not. It is not a matter for me at all. I wish merely to bring these experiments before the Committee. I think they tend to show that if milk is properly refrigerated—whether that is practically possible or not I do not wish to say—there is no need for the use of expressed in the subjoined tables (*see Appendix No. 35*), according to Thorner, as degrees of acidity, that is the quantity of one-tenth normal alkali necessary to neu-

7207. That being so, you would object to the indiscriminate use of boracic acid in milk?—Yes.

7208. Can you tell us any other conditions under which the administration of boracic acid is contra-indicated?—I think in the case of a complaint, where a person is already ill, or so seriously out of sorts from any disease that he is put on a milk diet, it should not be administered. Taking adult males, as I have already said, a man may take from 15 to 20 grains of boracic acid with his milk daily, and I cannot conceive an illness, associated with fever in the case of a person so seriously out of sorts, that he already had to be put on a milk diet, in which he would not be rather harmed than otherwise by its administration.

7209. Would you give boracic acid in the case of acute nephritis?—It is rather outside my province to treat acute nephritis, as I am practising as a surgeon; but, personally, if I had to prescribe for a patient of that sort, I should not give it. I should not expect any good to result from it.

7210. Have you any experience as regards the use of other preservatives than boracic acid?—Practically none.

7211. Have you anything to tell the Committee as to the use of salicylic acid?—My experience is not worth much. I have prescribed salicylate of soda, but that, of course, in any considerable dose produces very distinct symptoms—noises in the ears, and so forth—and you cannot continue the use of that beyond a certain point.

7212. Is that due to the drug itself or due to the impurities contained in it?—I think to the action of the drug itself.

7213. (*Dr. Tunncliffe.*) Would you regard the treatment, for instance, of infantile diarrhoea by boracic acid in suitable doses as being bad treatment?—Yes, I should say it was. Do you mean as an intestinal antiseptic?

7214. Yes?—I think in small doses it could produce no antiseptic effect whatever. It is very difficult to sterilise the urine with 20-grain doses. I do not think it could produce the desired effect given as an antiseptic. It is a very mild antiseptic, and you would have to give good big doses to get any antiseptic effect.

7215. You think its irritant action would be out of all proportion to its antiseptic action?—Quite so.

*Mr. A. R. Anderson.*

8 May 1900.

*Dr. P. Schidrowitz.*

7224. Would you just tell us what the experiments are?—I recently had an opportunity of taking and examining some samples of genuine milk, both cooled and uncooled, the temperatures of which were controlled from the time of milking and cooling up to the point at which the milk turned sour, or, rather, reached a certain point of acidity, or coagulated on being immersed in boiling water. Experiments were made (a) with milk which had been cooled to 10deg.—10.5deg. Centigrade immediately after milking, and (b) with milk which had not been cooled. Before I go to that, would you care for me to read out the references which I have with regard to the work which has been done on the refrigeration of milk?

7225. I think we have had practically all the historical part of the matter already brought before us, so if you confine yourself to your own experiments it will be better?—Certainly. The milk was transported from the country to London in a specially constructed churn provided with a water jacket and a maximum and minimum thermometer, and the experiments were started as soon as possible after the arrival of the same. In each case the milk was divided into two separate batches, one of which was kept at a temperature of 15deg. Centigrade, the other being incubated at 25deg. Centigrade. Each batch consisted of five samples: a being milk without any addition of preservatives; b containing formaldehyde 1 to 50,000; c containing formaldehyde 1 to 25,000; d boric acid 1 to 3,000; e boric acid 1 to 2,000. I do not suppose it is necessary for me to say why I took those quantities in view of the evidence which has been already given before the Committee?

7226. No, I think not?—From time to time 25 cubic centimetres of each sample were taken out of the containing vessel (glass bottles stoppered with cotton wool), diluted with 50 cubic centimetres of distilled water, and titrated with one-tenth normal alkali, using phenolphthalein as an indicator. The results of these titrations are expressed in the subjoined tables (*see App. No. 35*), according to Thorner, as degrees of acidity, that is the quantity of one-tenth normal alkali necessary to neu-

Dr. P.  
Schidrowitz.  
8 May 1900.

tralise 100 cubic centimetres of the milk. I have not expressed it as lactic acid, as the acidity of the milk is, to a great extent, not due to lactic acid, at any rate in new milk. There is practically no lactic acid at all in the latter. Of course, I am not giving that as information to the Committee, but merely as an explanation of why I did not give the acidity in terms of lactic acid.

7227. As the reason why you did not express the acidity in terms of the normal amount of lactic acid?—Quite so. According to Thorner milk coagulates on boiling when the acidity reaches 23deg., but in the milks examined by me the coagulating point was somewhat higher, being roughly between 25 and 26deg. Preservatives apparently slightly raise the point of coagulation. The following are the details of the experiments.

7228. Perhaps you will briefly summarise what your tables indicate?—The first experiment made with the mixed evening milk of eight healthy cows, two Jerseys and six Shorthorns, on a diet of mangels, hay, barley meal, and equal parts of cotton and linseed cake, was strained, and then rapidly cooled to 10·5deg. Centigrade. I may say that I actually saw the milking. The milk was then brought up to London by myself in the water-jacketed tin alluded to above. The maximum temperature attained by milk prior to starting experiments was 10·5 Centigrade. The experiments were started nineteen hours after milking, and the initial acidity of milk was 14·7deg. In the second course of experiments the only difference was that it was morning milk instead of evening milk, and the milking vessels were scalded immediately prior to milking. I was informed that the milking vessels were scalded from time to time as is usual, but I thought I would like to have them done immediately prior to milking in this case. The maximum temperature of milk prior to the experiments was slightly higher than before, namely, 11deg. Centigrade as compared with 10·5deg. in the first lot. In the third experiment the milk, morning milk, was not cooled in any way, but otherwise it was treated just as in the case of the first two lots. The maximum temperature prior to experiments was 29·5deg. Centigrade—that is to say, outside the body, of course—and the minimum temperature 22deg. Centigrade.

7229. (Chairman.) What season was this?—This was done about six weeks ago. The cows were stalled then.

7230. (Professor Thorpe.) Now, what do you infer from these experiments—what do they seem to you to teach?—The point at which the milk coagulates (measured by degrees of acidity) on immersing in boiling water is apparently somewhat affected by both formaldehyde and boric acid. The curdling point (natural coagulation) is very much retarded by both formaldehyde and boric acid. The degree of acidity is no absolute criterion of the quality of the samples. This applies chiefly to the samples containing preservatives—that is to say, a milk may have a relatively low degree of acidity and yet not be fit for consumption. Both formaldehyde and boric acid appear to exercise a selective influence on the organisms which produce changes in milk. This is illustrated by Experiment II., where apparently some organism possessing the power of causing a peculiar stench in milk was present. I cannot say how that organism, which I imagine was present, got there, as the cows were well in each instance, and they were healthy cows—there is no doubt about that.

7231. Do you regard it as an abnormal organism, or as one that ought to be present in milk?—Abnormal, I should say. In the case of the unpreserved (blank) samples, this smell did not become apparent, probably because the growth of the lactic acid or other normal bacteria kept the former from developing. On the other hand the sample containing formaldehyde 1 to 25,000 displayed a most unpleasant odour when the degree of acidity was still much below the ordinary limit. This odour became gradually less strong as the degree of acidity increased; and when the sample finally curdled, had quite disappeared. The phenomena noted above corroborated the evidence on these points already in existence. I do not desire to generalise widely from the facts recorded above, but they appear to confirm the opinion held by authorities with regard to adequate refrigeration in the first instance, and to the storing of milk at a moderate temperature in the second. I may say I have not had an opportunity of seeing all the evidence given before this Committee, but I do not know of any actual experiments which have been made with regard to the cooling of milk in connection with the use of preservatives.

7232. You mean as to the necessity of dispensing with them when the milk is cooled?—Yes, I mean parallel experiments.

7233. We have had a good deal of evidence on that point both direct and indirect?—My experiments tend to prove: (a.) That milk taken under rational conditions from healthy cows, may, if cooled after milking to 10—11° Centigrade, and subsequently stored at the moderate temperature of 15° Centigrade (a temperature which should cause no difficulty except, perhaps, in exceptionally hot weather), be kept sweet for about sixty hours after milking. That milk which has not been cooled, but otherwise treated in the same way, will not keep for more than roughly half this period. That milk which has not been cooled cannot be kept for the same period as cooled milk (without preservatives) even by the use of formaldehyde in strength 1 to 50,000 or of boric acid 1 to 2,000, and that although the use of 1 to 25,000 formaldehyde keeps down the acidity even in uncooled milk (kept at 15°) for a very long time, yet it by no means follows that the milk remains normal or fit for food purposes. That milk which has been cooled in the first instance to 10–11°, but is subsequently exposed to a high temperature, will not keep longer than thirty to thirty-five hours after milking, or ten to twenty hours after exposure to a high temperature (summer heat), and that under these conditions relatively large quantities of preservatives are ineffective over any length of time. That milk which has not been cooled, and is subjected to a high temperature will only keep for a very short time (ten to twenty hours after milking), and that under these conditions also preservatives are of little use. I may say that although the numbers given in the above remarks would naturally vary with different milks, yet I believe that broadly speaking they would hold good within reasonable limits. I believe that a regulation providing for the adequate cooling of milk for sale (I would suggest 15° Centigrade as a minimum) would be of very great benefit. I have said 15° Centigrade, on account of the work of Soxhlet and Enopf, who showed that above 15° the multiplication of organisms becomes very rapid, while below 15° it is moderate.

7234. Then, if we may generalise from the whole of the evidence you have given us, the inference is this: that you say provided means are taken for the adequate cooling of milk, you see no reason why the common preservatives which are mentioned should be used?—Yes, that is what I wish you to infer from my evidence.

7235. (Chairman.) When you say that you recommend regulations for the adequate cooling of milk, do you mean statutory regulations?—Yes, quite so. I mean a legal measure, passed and enforced for the cooling of milk.

7236. Immediately after milking?—Yes, immediately after milking.

7237. It would be rather difficult to enforce, would it not?—I think in some cases there might be a difficulty, but I do not know that there would be any great difficulty in cooling to 15° if there is an adequate water supply.

7238. I do not mean in that respect; but it would be rather difficult to enforce the regulation. How would you propose to enforce it over a district supplying a creamery where you could not have inspection in each part to see that the regulation is carried out?—I should think a visiting inspector would be sufficient to control the matter if the water supply is adequate, and if the cooling apparatus is adequate.

7239. Who would appoint him? What I mean is it is no use making recommendations unless you have seen how they can be carried out?—I quite see that, but at the same time I do not know that I am fully qualified to give any opinion as to how they should be carried out, but I do not see any very great difficulty in carrying them out if a law were passed that milk should be cooled to such and such a temperature. Then I suppose anyone who had not an adequate water supply would not be able to continue sending his milk up to the creamery or to the town as the case may be.

7240. But I put the difficulty before you. Take a creamery which is supplied by 50, or 80, or 100 farms. How could you enforce the cooling of milk in all these small farms?—I should start from this, that an adequate water supply is at present, I believe, supposed to exist in every dairy, and if there is an adequate water supply you would have very little difficulty in cooling the milk to 15°.

7241. But that is not the difficulty. I have not said that there would be a difficulty in cooling it. The difficulty would be in enforcing the cooling. However, if you recognise the difficulty that is all I want?—I daresay there would be some difficulty, but I do not see that there would be an unsurmountable difficulty.

7242. It involves the appointment of inspectors?—Yes, quite so.

7243. By whom are the inspectors to be appointed—by the Local Government Board?—I take it that would be the proper body, but really I would rather not give an opinion upon that.

7244. You have not thought that out?—No, I have not thought that out.

7245. (*Dr. Bulstrode.*) May we take it that your experiments tend to show that the lactic acid-producing bacteria are less resistant to preservatives than other bacteria—there may be bacteria which may produce but results, but the presence of which is not detected by acidity?—Quite so.

7246. That is the drift of your evidence?—Yes.

7247. (*Dr. Tunncliffe.*) I should like to ask just a question with regard to beer. Have the conditions in any way altered since the sitting of the Beer Materials Committee?—With regard to the use of preservatives do you mean?

7248. With regard to any condition whatever, as far as you know?—I should say that the use of salicylic acid is decreasing if anything, but I do not know that there has been any other very great alteration since then. The use of sulphites is increasing—there is no doubt about that, and the use of salicylic acid is decreasing, but apart from that I do not think there has been any great alteration.

7249. You have done nothing in the matter of preservatives in beer since the evidence before the Beer Committee, which you would like to bring before this Committee, have you—there is nothing fresh, is there?—No, there is nothing fresh.

7250. Now, with regard to the question of milk. Any regulations which might be enforced with regard to the cooling of milk at the time of milking would not be very potent if an arrangement were not made for cooling milk during transit, would it?—I think that initial cooling would help a very great deal even if no special precautions were taken during transit, but it would certainly be a great deal better if precautions were taken during transit as well. If you reduce the temperature, say, to 15° to start with, by the time the milk reaches town, say, 40 or 50 miles off, it will hardly get to a very high temperature; at any rate nothing like the temperature that it would be at if it had not been cooled.

7251. What I wanted to ask you specially was this: Do the remarks you make with regard to the use of pre-

servatives apply to the present haphazard method of treating milk by the railway companies?—To a very great extent certainly. I certainly think that if cooling chambers were provided, as they are, I believe, on some parts of the Continent, it would be a very great help, but I think the initial cooling of the milk is the more important matter.

7252. (*Chairman.*) Why do you fix 15°?—I fix 15° because, in the first place it would be a temperature which would not be very difficult to attain, and in the second place because there have been some experiments made, as I believe I have said, by Soxhlet and Enopf, which prove that up to 15° the multiplication of organisms in milk is not very rapid, and above that it becomes very rapid, and there is a table which I give here of the period of coagulation after milking when kept at various temperatures. When kept at 17½° it coagulates within three hours after milking; at 15° within 88 hours, and at 10° within 99 hours, so that there is no very great difference between 15° and 10°, but there is a very considerable difference between 17½° and 15°, and that is why I suggested 15° C.

7253. 15° is higher than the normal temperature of spring water?—Yes.

7254. (*Professor Thorpe.*) 15° is the average temperature in this country?—Yes. I think spring water would be probably a little below 60° F. on the average.

7255. (*Chairman.*) There would be no difficulty on the average in reducing milk to that temperature, would there?—I think not, except perhaps in the very hottest weather, and that would occur very seldom.

7256. (*Dr. Tunncliffe.*) What is the maximum temperature that your maximum thermometer recorded during transit?—In which instance.

7257. In the maximum one?—That was in the uncooled sample, of course. The maximum temperature recorded was 29·5°.

7258. That is Centigrade?—Yes, Centigrade.

7259. Was that in February or March?—In March last.

7260. In the cooled sample what was it?—In the cooled sample the maximum was 11°, and that, of course, had been cooled to 10·5°; it had only gone up about half a degree, and, of course, it was in a vessel which was enclosed in a water jacket.

7261. So that really it was not comparable with the transit of milk under ordinary conditions for that reason, and partly from the season of the year?—No, hardly.

Mr. HENRY SYMONS, called; and Examined.

Mr. H.  
Symons.

7262. (*Chairman.*) You are a partner, I believe, in Messrs. John Symons and Co.?—Yes.

7263. They are cider merchants?—Yes.

7264. And you come to tell us what is the practice with regard to the employment of preservatives in cider?—Yes.

7265. Is it universal?—I do not know that it is universal, but I think some of the best makers use a very small quantity.

7266. What is the material they use?—Some use a little salicylic acid and some use saccharin; some use the two combined, I think, and others use sulphite of lime or soda, and various other compounds are used, I think.

7267. What do you mean by saccharin?—The soluble saccharin that is sold.

7268. Do you mean a product of coal tar?—Yes.

7269. That is what is known as saccharin?—Refined saccharin.

7270. I ask that because I have here a prospectus setting forth the advantages of saccharin, and in particular of the Tigress Brand?—Yes, that is the same thing as soluble saccharin.

7271. Is it the identical material?—Yes.

7272. Are you quite sure?—I consider it is. If it is what is sold by Messrs. Wilson and Salomon that is very much the same. It is supposed to be made by another process, but I consider them to be very similar. I do not think it is used very largely.

7273. Do you think it is necessary to use preservatives in cider?—I think many speak against preservatives, but I may tell you I have studied the matter from Pasteur's 3017.

researches in France in 1876. In fact, I read the book myself, and about 1880 or 1881 I wrote him to know if I should do right to publish it in England, and he wrote to say he was engaged for the French Government, and he declined to allow it, but I may say I have studied the matter for the last twenty-five years. I have studied the germ theory thoroughly, and I find that the judicious use of preservatives is good, but they must not be used to the extent that some people recommend, even the Germans or the French. If they are used sparingly under certain conditions, depending partly on the state of the liquor, and on the season of the year, and the state of the fruit, and the age of the cider, they are not harmful, but we have to take all these things into consideration. My opinion is that where you have a cider that is rather low in alcohol, which some of our ciders are in some seasons, a very small proportion, say one-eighth of an ounce per pipe of 116 gallons, is a very small quantity, but still it has an effect. In the case of viscous fermentation—that is the ferment that causes the turbidity—I mean, of course, the sick fermentation, if the germs are allowed to grow in the liquid it is difficult under some conditions in the hot season or from climatic changes to prevent them growing, and if you use a very small proportion of preservative it is done to prevent their growth. I may tell you that now I am trying to separate some germs from different apples in order to be able to counteract the effect of the special germ that gives us the trouble—the putrid germ—or I will not call it the putrid germ, but it is the one that gives the characteristic of sick fermentation. In fact, I have known the liquid to be good one day and by the next day to be sick of ferment. I do not believe in using preservatives to prevent acetic acid. I think if people get it it shows great negligence, and it would require a great deal to

Mr. H.  
Symonds.

3 May 1900.

prevent acetic fermentation. The vinegar ferment is, of course, stronger than the other, and hence it would require more to prevent it.

7274. What produces sick beer or cider?—It is the wild yeasts or disease ferments—it is called viscous and sick fermentation. It is akin to putrid fermentations. If among those present there are any chemists they will be well aware I presume of that, and they will understand it. I suppose some gentlemen here thoroughly understand fermentation, and those who do would say that if those ferments are found in cider or beer it would be advisable, if possible, to arrest their growth. If you get cider with rather a low percentage of alcohol and a good deal of body—that is, cider that would weigh from 10 to 12 lbs. per barrel, it is very difficult to preserve it. I may say I met Mr. Lott, of Burton-on-Trent, three or four years ago, and he was very much interested in what I was doing. You are aware that some apples resist decay very much longer than others, and if you take the germs from those apples that stand longest and use them in fermenting liquor containing unsuitable germs or those that are not very strong and healthy, but which are short lived, I have no doubt they would overcome and eat up, so to speak, or crowd out, the inferior ones. I may tell you that I find that the germs are first produced on the leaves, and I found out last year that each apple leaf contains many different germs, and I have made cider from germs produced from one apple leaf that will be quite different in character from the germs produced from another apple leaf.

7275. But at present you have not arrived at any definite solution?—Yes; through a series of experiments extending over many years. I remember I was one of the first to study it when I went out to America twenty years ago. I went out to America twice. We formerly shipped a good deal of cider there, and we thought of putting up mills, but when we shipped the cider we found it would not stand the carriage at all. I presume this will not be published—it is quite private here, I suppose.

7276. You must not tell us anything you do not want to be published?—I should imagine that this inquiry should be private; you can hardly expect any one who has had a good deal of experience in fermentation to come and give away all his experience for nothing to be published to the world.

7277. This is a public inquiry, and, therefore, you must use your discretion as to what you tell us?—Then I fear I shall not be able to go very far.

7278. I gather that you have used preservatives hitherto?—Under certain conditions.

7279. What are those conditions?—The conditions are that if you have a liquid, say, under a certain percentage of proof spirit, which you find on testing is unstable or is likely to be when sent out for consumption.

7280. But I cannot go into all these details?—These are the things that should guide you in forming an opinion, if I may be allowed to say so.

7281. I will tell you what I want to get from you. You say that the use of preservatives in the manufacture of cider ought not to be prohibited?—I certainly think it ought not to be prohibited, but there should be limits given.

7282. As to the quantity used?—As to the quantity used. Certainly it should be so, and that is very important. You know if you preserve fresh meat—taking a piece of pork—you would hardly object to sprinkling a little salt over it, or, in cheese-making, you would not prohibit salt which is used as a preservative.

7283. I think we may dismiss that argument by the consideration that salt is a natural food, and although it is a preservative, it is not a preservative in a technical sense?—No, I quite see that difference. I should certainly object to a large quantity of preservative being used; but under certain conditions it is certainly advisable to use it, because preservatives prevent poisonous fermentation, which is very deleterious for any one to take into one's stomach. Salicylic acid is, in a sense, food, but that must not be largely used, and cider contains an acid which, to some people, is a specific almost for gout and rheumatism, and to others is quite the reverse. Salicylic acid, used in very small quantities, is a specific for gout, and certainly it would do more good than harm if it were used in very small quantities; but it must not be used in the proportion that the Germans use it.

7284. More good than harm to what or to whom?—To the human body—to the human system.

7285. Then you assume that everybody would be better for a daily dose of salicylic acid?—No, I do not; but I

would rather have that than have cider liable to go wrong. A daily dose would be a very small quantity. The quantity would have to be so infinitesimal that it would be easy to get over the purpose required, that is to prevent this putrid fermentation, if I may call it so. We do not use it universally, but only at certain times, because, as you know, things change, and the seasons change, and the fruit is different. Half the quantity that we use would be taken up in the wood and the lees, and our cider would only show a trace. The main portion would go into the cask to preserve the wood and kill the bad germs in the wood, and be taken up with the lees. So that as the cider came up to the public it would only contain a trace. But we do not use it universally. You were speaking about prohibiting it, and I say I certainly think that there would be an objection to prohibiting the use of it, because I believe it does more good than harm; but I suggest that you should have a standard, and that you should not allow more than a certain quantity.

7286. Can you state any limit?—Yes. I would say it should not be more than from half an ounce to an ounce per 116 gallons.

7287. Of what?—Of salicylic acid. It is a very, very small quantity.

7288. And what of saccharin?—Of saccharin from one-eighth to a quarter of an ounce.

7289. Do you think that that is a proper use of saccharin as given in the prospectus to which I have referred; it is recommended for cider, and for beer, amongst other things. It says: "As a Cure for 'Sick' Beers. Even when such a dubious lot of beer already begins to show signs of incipient 'taint,' there may yet be time to save it by quick action in introducing, as may be needed, from one to two ounces of saccharin ('Tigress' Brand) per 500 gallons, and thereby arresting the souring process and at once making the beer drinkable and marketable"?—It would be too late to do it once fermentation has set in.

7290. And that would apply to cider also?—Yes; and I should say we should not use it in the manufacture, but after the manufacture, and before it is sent out to the public. Most of it would go off, and some short time of from one to three months before it is sent out to the public I should advise it being used. A great deal would go out into the lees and into the wood, and purify the lees and purify the wood. In making these preservatives people use sometimes more than they should do, and, therefore, I should thoroughly recommend that there should be a limit placed upon its use, and if there is more than that limit shown there should be action taken. As to salicylic acid, I ought to mention that I found it a good preservative in certain cases, although we do not use it universally; but when it came before the Courts in 1886 the decision was given against the prosecution. A number of experts showed that it did more good than harm, and the case was dismissed. I go on that. There was a sufficient number of experts called to show that the salicylic acid used in cider did more good than harm, and so the case was dismissed—there was no decision against it; and, therefore, one would naturally suppose after that that it would be right to use a certain proportion of it; but it would be only the very best makers who understood the business that should be allowed to use it.

7291. You are indicating rather difficult lines for legislation, are not you?—Yes, certainly.

7292. Would you have a competitive examination in cider-making before anybody was allowed to use preservative?—No, I should not do that; but our process is more difficult than brewing, because it varies more.

7293. Are you aware that evidence has been given before us on behalf of the cider industry that it is quite possible to make cider and perry without preservatives?—I have heard of a gentleman being here who said that, but he has not had very much experience yet. At Butleigh, where they have been making it this last year, a large proportion of cider went bad. The time may come when we shall be obliged to use them in order to get to perfection. If you get a thing up to perfection, the thing being very sensitive, it is like fever amongst cattle—very often it attacks the best beasts; and so if you get a very delicate beverage working up close to the maximum in regard to sweetness and palate flavour, it is most likely to go wrong when the fermentation takes place from this particular germ.

7294. (Professor Thorpe.) I suppose you would not say that the bacteriology of cider manufacture was quite as—I think it is not quite.

Mr. H.  
Symons.

8 May 1900.

7295. I suppose you are aware that it is now generally recognised that the reason why beer goes wrong in fermentation, or in its after-fermentation, is due to the presence of foreign organisms—what you call germs?—Yes.

7296. And that if care is taken to exclude those germs the evil to beer does not arise?—Yes.

7297. Perhaps you are aware that now a large number of the breweries make what they call pure cultures?—Yes.

7298. And that they can obtain these things commercially?—Yes.

7299. Using these pure cultures you know they find there is no necessity whatever to add any antiseptics or preservatives to the beer?—You can make a pure beer certainly from single-cell yeasts. I have some cider yeast that I got from Professor Jorgensen in tins five years ago, and it is living now, although he said it must be used immediately. I examined it about two months ago, and found it well preserved, but it is the after influences that are important.

7300. Let us do one thing at a time. Do you tell the Committee that the Copenhagen Institute is now in a position to supply the pure ferment culture required in cider manufacture?—No, I am not aware that it is. I sent some apple pulp to get some isolated pure yeast, and I made some isolated yeast myself; that from Copenhagen was not so successful when tested under the same conditions and influences as my own selection, and consequently I discarded the use of it.

7301. You have been able to identify an organism which is frequently concerned in the manufacture of cider then?—Yes, certainly—several.

7302. If you conduct the fermentation of cider with this pure single organism, would the subsequent effects that you have described take place?—They vary very much. Some cells—that is, some yeasts—are short-lived, and would die quickly, and if they die what becomes of the liquor.

7303. Do you mean to tell us then that it is not possible to get a pure culture in the case of cider manufacture in a manner similar to the case of beer?—You may get it, but unless suitable the yeast is made up to a certain gravity, under suitable conditions, and with the proper quantity of acid, and the same quantity of sugar, it is not likely to stand. Cider is not made as in a brewery, where you have one building, and all the temperatures can be made to vary, by cold and ice or cold air chambers, or cold or warm air. Cider is made in the open country in cellars, in which you get great variations in temperature. Therefore, the conditions are not the same.

7304. But the conditions could be at all events brought very largely under control, could not they?—They are largely under control, certainly; but these yeasts vary. Each apple produces a different yeast. I have been trying to find out why one apple should be sour and another should be sweet, and I think that might be found out. I consider that it is the germ in the wood that makes the difference. I have gone, as I told you, so far as to find out that germs are on the leaves. Where do they come from—from the buds or the sap originally? It has always been known hitherto that they exist on the skins of the apple, and I have proof now that they come from the leaves to the apple. Now, where do they come from to get on to the leaves—from the ground or the body of the tree? I consider they come from the body of the tree, brought up with the sap. If they do, there is something still to be said, and there is still further to go, because these germs are very different from one another. I have lots of different germs. Some will make a staple article, and others will not make a staple article. But we wish to make a palatable drink that the public would like. Some like one flavour and some another, and now we shall have to find out and discover the causes of the differences, and that is the work of time. These things cannot be found out in a short time—in one, two, three, or even more years. I have been at it now for 20 or 25 years, I might say; but we shall have to discover a strong yeast that, if used, will militate against what we may call this sickness. I think I may tell you I have three now out of the dozen that might do. I can scarcely speak from experience of its use, as I have only been at it two years, and two years is not sufficiently long to investigate it and show that it can be done. But if it could be done, we should very rarely resort to the use of preservatives. You know, in our old match-making process sulphur is used. Now we take out most of that sulphur after it has had its cleansing effect by applying boiled or baked apples; we put

3017.

in a certain quantity two or three times, and that absorbs the sulphur compounds. The lees and the wood take out some of it. After it has had its cleansing effect there is very little left in the cider.

7305. (Dr. Bulstrode.) Why do you limit the amount of preservatives in the cider?—Because, if there is an extra quantity used, it is useless. It might do the constitution of some people harm—I cannot say it would; but there is no use in it. I consider that if there is more than the proper quantity used, the manufacture has been faulty.

7306. What other preservatives besides salicylic acid, saccharin, sulphite of soda or lime are used? How much soda is used?—We should not use more than from an ounce to two ounces for a pipe.

7307. Do many manufacturers use more than that?—I do not know that they use any. Some do, I know, in America.

7308. You spoke just now of America. Do they use it much there?—Yes.

7309. How much do they use there?—They use about a third more.

7310. And in Germany?—I do not know what they use there. Of course, they use salicylic acid and saccharin largely.

7311. In what amounts?—They generally use about one-third more than I have recommended.

7312. Do you know the maximum amount of preservatives that has ever been used in cider?—No, I do not. I have never used at the very worst nearly as much as the Germans or Americans use.

7313. Are we to gather from your evidence that you do not think that a proper regard for cleanliness would prove a substitute for the use of preservatives?—No, I do not think it would. Certainly, cleanliness is of the utmost importance—it is a great thing. We use our racks and cloths, and a washing machine with two men to do nothing else than cleanse the plant and utensils, and we have special machinery for doing it, because it is absolutely necessary that the plant should be kept clean.

7314. (Dr. Tunncliffe.) Are you aware of any work being done in this country upon the bacteriology of milk and cider upon the lines that are being adopted with regard to wine? I mean, is there any attempt being made to get the pure culture of the aroma-giving bacilli, and to add them after pasteurisation to the cider?—Yes; I myself have done it very often.

7315. With what success?—I have done it with varying success. Some bacilli, I tell you, will produce an unstable liquid, and that is owing, I consider, to the yeast, if the germs are delicate or short-lived, and others will produce a more stable article. They give different flavours. I have a score of different flavours, I suppose.

7316. Where do the aroma-producing bacteria of the cider come from? Where do they grow principally?—It has always been thought that they grow upon the skin of the apple. Last year I investigated the leaves, and I had separated several sorts of yeast from the leaves and the apple, and I thought to myself, "Where do they come from?" They were not only on the skin of the apple. I thought it was very interesting to see if there were any on the leaves, and I found there were different kinds on the leaves, and, as I say, I asked myself, "Where do they come from to exist on the leaves? Do they come from the tree, or do they come from the ground, or do they come from the air?" My impression is that they may come from the tree as spores, in the bud, in the sap, in the blossom. But that is a thing to be investigated.

7317. But if that were thoroughly investigated, you would have no need for preservatives, because you could exclude those viscosity-producing bacilli. That is the point I understand Professor Thorpe was trying to put to you?—Yes, I know; but it is very, very difficult to deal with. When you get a super-solution, which sweet cider is, having a gravity of about 10 to 12 pounds per barrel, and only with about 4 to 5 per cent. of spirit—say 3 to 4 per cent.—it is extremely difficult to preserve that; and people will have the cider sweet. We sell three sorts.

7318. When you see cider going wrong, do you add salicylic acid?—No; I would not do that. I would do it before if at all. We have forcing flasks and an incubator for forcing, to see whether it contains these particular germs, and if I thought there were any signs of it, or if there is a doubt about it, or if we think it is likely to be a warm summer, along with other considerations which I need not mention, we should act.

Mr. H.  
Symons.  
8 May 1900.

7319. That is what I say; when you have indications that the cider is going wrong, whether by the gross senses or microscopically, you would add salicylic acid?—Yes; but I will not say we have indications. We examine it before the indications arise.

7320. But you must have indications in order to know it is going wrong?—You must have in the laboratory.

7321. I say microscopically?—Yes.

7322. And you add salicylic acid?—Not always.

7323. You add it as a preservative?—We often do.

7324. What do you say to pasteurising?—We have tried it ever so long since. I have pasteurised hundreds of hogsheads, but it does not work well.

7325. It is the means commonly adopted abroad, is not it?—It makes it very flat; it gives it a very insipid flavour. There is not much high-class light wine pasteurised now. It would not be used in this country, although it is used in France and Germany. The English will not drink what the French and Germans do.

7326. It is only the exception that you get these laboratory indications of cider going wrong?—Yes, it is the exception; we cannot always tell with certainty.

7327. Therefore you would require only to pasteurise cider exceptionally?—It would be too late to pasteurise it when it is quite ready for consumption like wine. The acidity in the cider would prevent it. You could pasteurise American or French cider with greater success than English cider on account of the greater acidity of English cider. It depends much on the soil it is grown on. Somerset is very different from Devonshire, and Hereford from Somerset. It is like the different breeds of cattle, for if you take a breed of cattle from one particular district and send it fifty miles away, it goes back, because the soil is not the same, and the conditions generally are not so favourable and the air is not so suitable. It is a breed of itself, which has grown up under certain conditions for a certain number of years, and it has attained perfection, and is found to be most suitable for that district. If you take a Devonshire Quarrenden apple it becomes different in colour if you send it to be grown in certain far distant localities. So you have to take all these things into consideration, and consider the situation. I do not advise, and I would not have it said that I advised the use of preservatives altogether for cider, because it would make people careless in the manufacture of it. But I say, do not prevent honest manufacturers from using a small proportion in case of necessity, because it is beneficial not only to themselves, but to the public, for if cider is sent out it is like beer; it is very largely consumed, and people are consuming a putrid thing sometimes. I will not say a putrid thing, but a thing analogous to that. It is like beer, and there were train loads of beer which went bad last year, and why, because very likely the makers had been depending too much on pure yeast and working too close to laboratory experiments which scientific men are sometimes apt to do, thinking the same result may be attained under different circumstances, sufficient allowance not being made for outside influences.

7328. (Chairman.) The cider industry is a very ancient industry, is it not?—Yes, very.

7329. But it is a progressive one—your knowledge in is progressive?—I think so. Our trade keeps just the same as it did. We do not increase very much in that respect, for, of course, there is undoubtedly a great deal of competition.

7330. But I mean your knowledge of the manufacture has increased, and is increasing?—I think so, certainly.

7331. You have not attained perfection yet?—I cannot say. It is very difficult to say what is perfection now in these days. I think we have almost attained that as far as keeping quality goes. We do by far the largest trade, and I can consider it is by having such a knowledge of the business so many years ago that has enabled us to attain this position. I know the time when we lost thousands of pounds, but by looking at it more scientifically we have overcome that.

7332. Through your experience of the business, your knowledge of cider making has advanced?—Yes.

7333. Owing to the application of the results of bacteriological research?—Yes. I may say our forefathers used to drink cider in a very rough and acid state; but then they were living in the country, and taking plenty of exercise in the open air, so that their stomachs could stand it—they could do with that acidity.

7334. I was asking about the manufacture, and not about the consumption, and I repeat my question. During your experience, extending over 30 years about, I think you say the manufacture of cider has been very much improved. Is that so?—It is very difficult to say. I was reading a book dated 1828 the other day, and I thought to myself our forefathers were not fools. The writer recommended specific gravity of 1028 to 1033, which we find the best suited now for the public. So that in these early days there were some who understood their business.

7335. Then are you prepared to say that the only advantage acquired during your researches bacteriological and otherwise is of no use?—I would not say that for a moment, because I know a lot of my old men, my old hands, know what would produce certain results, but they do not know why, and in my case I was not satisfied before I found out why those results were obtained. I saw them there working at it all their lives, and knowing exactly the process, and what will produce certain results, and knowing which is the best process to use in order to get these results, but they cannot say why these results are produced, but I can tell why they are produced, and for a great many years I have known exactly from first to last both bacteriologically and chemically, why they are produced. Therefore, if science and practice agree, you cannot do better, I say. But you know the seasons vary, and the fruit varies, and the temperature varies, and therefore I say it is very, very difficult to tell what will be the result in a given case. I do not wish you to understand that I would advise the universal use of preservatives. I should certainly say they should be used under certain limits, and let these limits be small. If you allow too much alcohol the acid becomes too pronounced or apparent, which would not please the public taste, and I daresay the Government would not wish so much alcohol as that to be produced.

## TWENTY-SIXTH DAY.

Monday, 14th May, 1900.

PRESENT:

The Right Hon. Sir HERBERT MAXWELL, BART., M.P., F.R.S. (Chairman).

Professor T. E. THORPE, F.R.S.  
H. TIMBRELL BULSTRODE, Esq., M.D.

Professor TUNNICLIFFE, M.D.  
CHARLES J. HUDDART, Esq., Secretary.

Dr. G. VIVIAN POORE, M.D., called; and Examined.

Dr. G. V.  
Poore, M.D.  
14 May 1900.

7336. (Chairman.) You are a Fellow of the Royal College of Physicians and a Member of the Royal College of Surgeons?—Yes.

7337. You are physician to the University College Hospital?—Yes.

7338. Also Professor of Medical Jurisprudence and Clinical Medicine at the University College, London?—Yes.

7339. I believe you have directed some attention to the use of chemical preservatives in food?—I cannot say

Dr. G. V.  
Poore, M. D.

14 May 1900

that exactly; my knowledge is that of a physician seeing the effects of food.

7340. Have you come to any opinion as to the possible effects of their indiscriminate use?—I think that it ought to be not permitted to add any preservative to food, unless the nature of the preservative and the quantity added be fully stated. I think that, besides the positive harmfulness of certain preservatives, the negative side of the question is most important; that there ought to be no risk of mistaking preserved food for fresh food; and that the want of fresh food cannot but have a very harmful effect on the health of the community—notably of children.

7341. Does that arise in your opinion from the action of these chemicals on the digestion, either directly or by retarding digestion?—I think it is impossible to say. I am making a plea, if I may put it in that way, for our ignorance on the matter. Scurvy is one of those things concerning which we are yet ignorant. I take scurvy in its broad sense. All that we know is that, when a community is kept with the absence of fresh food for a long time scurvy results, and the general level of health falls in many ways. No chemist and no physiologist has yet given us a satisfactory explanation of the cause of scurvy, which is a very great fact; all that we know is that if you keep a community on preserved foods too long it becomes scorbutic. It was thought at one time, as I need hardly remind you, that salt was the cause; but I think that is exploded. It was suggested at one time that if stock fish, that is to say, fish that were simply dried, were substituted for salt fish, that our sailors would escape scurvy; but that again was found to be not true. It is the absence of fresh food in some form, notably fresh vegetables, and to a less extent, fresh blood or absolutely fresh milk, that leads to scurvy; it is those things that are anti-scorbutic. It is the fact, I believe, that a child at the breast has never been known to contract scurvy. I do not know what may happen in a community severely stricken, like besieged towns and so forth; but that I take it is a fact which I find stated everywhere, that a child at the breast does not contract scurvy.

7342. Do you draw any distinction between vegetables preserved aseptically and hermetically sealed, and vegetables preserved by the use of a chemical?—Yes. I should say that those preserved by chemicals might be positively harmful, according to the chemical used. Those simply preserved aseptically would have no positive harm, although they might have the negative quality of not being able to keep off scurvy.

7343. Is it not the case—it is a matter of popular belief, at all events—that preserved vegetables, bottled vegetables do prevent scurvy?—Yes, it is a matter of popular belief, but I think it has been found that preserved vegetables have failed; I think Nansen found that they failed. They have not the anti-scorbutic power of the actually fresh vegetable. It is well-known, of course, that the leguminous things—dried peas and beans—do not prevent scurvy, although of course drying the things is an anti-septic way of preserving; but that these leguminous plants, dried peas and beans, do not prevent scurvy, has, I think, been proved again and again. I should be very sorry to trust absolutely over a long voyage to preserved vegetables entirely, without some fresh meat, fresh blood, or absolutely fresh milk—I think there is a certain anti-scorbutic power in them.

7344. It is a fact, is it not, that there is a much greater immunity from scurvy generally, both at sea and on land, than there used to be?—Clearly; and that is due, first, to the great precautions that are taken, and then the voyages are not so long.

7345. Except when you go into the Arctic Circle?—Of course. Lime juice seems to be one of those things which retains its anti-scorbutic power for a long time; although occasionally it has been found that lime juice which has been doctored—I do not know with what, but with a preservative—has proved a bruised reed rather to lean upon for the prevention of scurvy.

7346. Then in your opinion the object that ought to be kept in view is the supply of food to large communities in an absolutely fresh condition?—Yes, certainly.

7347. And there is a distinct difference between fresh food?—And stale food.

7348. And so-called fresh food, which is only kept fresh by means of a preservative?—I should say most certainly there is a difference.

7349. Again I will ask you to tell us anything that you think bears upon the question; I will let you take your

own line?—With regard to milk which is a very important thing, if you add a preservative to milk which is perhaps tasteless, there is not only the harm done by the preservative to the milk itself, but it very soon ceases to be fresh milk. Of course the milk which is drawn by a suckling animal from the breast of its mother, which has never been exposed to the air, which has never been lowered in temperature, the constituent parts of which have never been allowed to separate, we must look upon, I think, as a different thing from milk which has been artificially cooled, exposed to the air, whether before or after sterilisation, and allowed to separate into its constituent elements. I do not think we can look upon those as the same things. Clearly it is the experience of all physicians and the experience of myself that children who have been fed in the natural way never manifest scurvy, and seldom manifest the rickety condition. It is when you get artificial feeding—and artificial feeding, of course, involves all those points I have raised, namely, the alteration of temperature, the exposure to air, and the separation of the elements—that you get those conditions. There are many adults who can take milk and cannot digest cream. That is a thing which has often come under my own notice, and it must make us pause in considering what the effect of separating the constituent of milk or allowing them to separate may be. What I am making is a plea for our ignorance that we do not go too much ahead of our facts and think that because a thing does not stink therefore it is fresh. There is a distinct difference in my mind.

7350. I am going to take you up on that observation that you think we must not go ahead of our facts. I see in the synopsis of your evidence that you imply that certain conclusions—you do not draw them, because you say you are unable to define them—may be drawn from the consumption by wild animals of warm meat?—All that I say about that is that it is a fact to make us pause; I do not wish to go further.

7351. Is it a fact, is it the case that animals that live on warm meat develop more energy than others?—They develop a very extraordinary energy, as you will have seen if you have watched, as I have, domestic animals—and I am quite sure you have. When, for instance, a cat is having a litter of kittens she shows an exceeding anxiety to get out and get live birds. The same thing with a bitch when she has a litter of puppies; I have noticed several times the exceeding anxiety of the animal to get out and get raw food. I cannot say more than that, and I did not mean to say more than that. It must make us pause. Really all that I am asking for in my evidence is that we do pause and consider how ignorant we are on these subjects.

7352. Is it not a fact that some animals who live indifferently upon fresh meat and carrion develop an equal amount of energy—the golden eagle, for example?—Does it live entirely on carrion? It takes fresh meat, does it not?

7353. Yes, indifferently—it takes fresh meat or carrion?—That may be. That is not quite the point. Of course I do not object to people taking high venison or rotten cheese or anything they like, but I think we all want a certain modicum of really fresh food. I think every animal wants a certain amount of really fresh food. Our horses are turned out to grass once a year so that they may get some really fresh food, and it is difficult to say on chemical grounds perhaps, what it is that a horse gets by being turned out to grass; but I think it is a generally accepted fact that it is necessary.

7354. I cannot accept that statement. I think if you ask any hunting man he will tell you that he regards the annual turning out of horses to grass as most pernicious to vigour. That old system is universally discarded now; I can speak as an old hunting man?—Of course I have no right to push that, but I travel about in the country and see horses taken out to grass, and I know that they are turned out when they are sent into the country. We see how exceedingly greedy a horse is after a little fresh food. See what a horse will do for a fresh carrot, for instance. Do you give your horses fresh carrots?

7355. Yes?—Perhaps the carrots may take the place of the grass. I do not say the grass is the best thing, but I take it that you, as a hunting man, always give your horses some carrots?

7356. Yes?—Very well then, the carrot, I think, takes the place of the grass.

7357. I do not want to labour the point, only I think it must be admitted, must it not, that some animals living exclusively upon carrion, such as the vulture, possess extraordinary powers of endurance and flight, with an enor-

Dr. G. V. mous amount of animal energy?—What do you mean by  
Poore, M.D. carrion?

14 May 11. 0. 7358. What the vulture eats?—The vulture eats fresh meat, does it not? The vulture will come to the body however fresh it is.

7359. Its staple is carrion, because in the climate where the vulture feeds meat becomes carrion as soon as the life is out of it?—You are taking me out of anything of which I have special knowledge, but one reads, for instance, that in South America an animal dies and the condors are there, although they may not be seen at the time, within a few hours. I should take it that a body eaten within a few hours of death would have some anti-scorbutic property—would have some element of freshness in it.

7360. Possibly in this climate, but I do not think so in hot climates?—I do not know.

7361. I interrupted you. Will you kindly go on?—My statement to you is generally a plea that there ought to be no confusion between fresh food and stale food; and I go so far even as to include frozen meat in the category of food which is no longer fresh. We ought to know whether it has been kept a day or a month, or any length of time. Clearly my own experience is, and that of others is, that food preserved in that way loses its flavour. It all depends how long and carefully it has been done, but you do not always get the maximum amount of care with regard to temperature and so forth, and it is an undoubted fact that there is a great deal of frozen meat which loses its flavour and becomes flabby and generally unappetising. Of course, the great factor appetite must never be lost sight of; some things are appetising, some are not. A new-laid egg—I have taken that as an example—is appetising, and what the cook calls a shop egg to most of us is nasty; we do not care to eat it, although we get very little else in London. The same with butter; a really fine sample of fresh butter is an exquisite thing, beautiful in flavour, and intensely appetising; but I think we get very little of it in London. I should draw a very wide distinction between the two. I cannot say that one is poisonous and the other is not, because that is not true; and I do not want to be represented as saying that preserved foods of all kinds are not most necessary and are not most important articles of diet. I am only asking that there should be no confusion permitted between what is really fresh and what is preserved.

7362. In short, salt meat speaks for itself?—Yes.

7363. And these cryptic processes do not?—That is an excellent phrase—these cryptic processes do not speak for themselves.

7364. On the other hand, I suppose you would admit that certain changes go on in milk inimical to digestion or to the general health which are arrested or retarded by the use of these preservatives?—Of course, if the milk is prevented from going putrid that is a distinct advantage.

7365. Or if the multiplication of noxious germs is prevented?—Yes, I quite admit that. But there is another side to the question. Take milk that has been heated, semi-churned, run through tubes, and so forth; I cannot regard it as at all probable that that milk is the same as the milk drawn direct from the mammary gland of the mother into the mouth of the offspring, because in the latter case the milk drawn is really a living fluid; it has never undergone any exposure at all, and clearly it is as a rule very much more digestible for the child. There are cases where the child cannot feed from the mother, indigestion comes on, and we have to adopt artificial feeding, but those cases are exceedingly rare. When you come to the artificial feeding of a child, then the difficulties of digestion are exceedingly common, and you have to dilute the milk and alter the food and so forth. Then again there is the great danger of physicking a mother while she has got a child at her breast. If you give drugs to the mother or the wet-nurse the child is upset, notwithstanding the exceedingly small quantity of the noxious element which must be in the milk drawn from the breast. That again must make us pause, I think, as to the possible effect of preservatives or chemicals added.

7366. Now you have introduced a new element which has hitherto been advocated as an alternative to the use of preservatives. I understand you to be suspicious of the effect of pasteurisation?—No, I would not say suspicious. I think that is putting too strong a term on it. I do not think we ought to regard milk that has been withdrawn from the body as at all a substitute for milk withdrawn direct from the breast under any circumstances. As to what the effect of pasteurisation may be, nothing in this world is entirely for good nor entirely for evil, and I quite admit the advantage of sterilising milk; but there

may possibly be another side to the question; it cannot be regarded as the same thing as fresh milk.

7367. If you have a declaration as to the presence of chemical preservatives, would you also on the same grounds require a declaration as to the pasteurisation of milk?—I would. It might increase the sale, although certain people might hesitate to use it exclusively, that is all. If milk had been pasteurised it ought to be so stated.

7368. Do you hold any opinions as to the use and possible effect of colouring matters of various kinds in food?—First of all, I cannot see why they should be used. Of course you have the very great danger that in place of the vegetable colouring, such as spinach and so forth, aniline colours may be used, and I should say they are all harmful—there is no question about that. It is a process anyhow not to be encouraged. I am told that colouring matters are added habitually to butter; I think really it ought to be stated.

7369. You are aware no doubt of the popular prejudice in favour of a uniform quality. A customer does not like his butter white one day and yellow the next?—That is so, but still he ought to learn that nature is never the same—she varies; and directly you get a thing of uniform quality the sensible man must know it has been doctored. Some years ago they advertised sherry of uniform quality year after year, quite irrespective of the alteration in the vintages, the climate, and so forth. That only appeals to me in one way—a uniformity of quality must very often mean that there has been some process adopted for making the quality uniform either in milk or in anything else.

7370. We have had a good deal of evidence about the use of sulphate of copper in the colouring of green peas?—That is perfectly indefensible.

7371. It has been urged that the quantity is so minute that it cannot hurt anybody. You do not believe that?—No, I do not.

7372. I may take it you would reject it in any quantity, however small?—In any quantity, just as I would lead, no matter how small.

7373. (Dr. Bulstrode.) Your evidence would rather amount in a sense to an attack upon our urban conditions, would it not? It would have a tendency that way?—Of course, our urban conditions make it so exceedingly difficult to get fresh food that it becomes exceedingly important that the people should be able to know when they are buying really fresh food, even though they had to give a much higher price for it.

7374. I suppose you will admit that, as we are at present tending, we must year by year, if the population goes on increasing, consume an increasing amount of preserved food of one or other kind?—Yes.

7375. And therefore it comes to be a question as to what is the best form of preservation, rather than a question of getting absolutely fresh provisions?—Of course, that goes without saying. I think that we want to find out the best mode of preservation. I say in my synopsis, and wish to repeat again, that preserved food must always have its legitimate place in all dietaries, and if the urban populations, as is evident, are getting more and more dependent upon preserved food, then I think it is very essential they should know where they can get fresh food.

7376. Your objections to the use of preserved food would to some extent be met by a due proportion of really fresh food, would they not?—Yes, clearly—a due proportion. But what that due proportion is I think we are not prepared to say yet.

7377. Would you advocate the labelling of every means of preserving?—Yes.

7378. Salt?—When it is necessary. You buy a ham and you know it is a ham, and know that it is preserved. That is a matter of common knowledge. We call a ham a ham and we call pork pork; but if you sell me a certain thing that is preserved as fresh pork then I think it ought to be stated.

7379. You do not quite know what the ham is preserved with, do you?—No, it is a matter of flavour very much.

7380. Would you advocate that where salt is used as a preservative that fact should be stated?—I do not see why it should not. Let it be stated that the article contains 5 per cent. of salt, or whatever it may be.

7381. And so with saltpetre, if there were any. Nitrate of potash in it—would you have that notified?—I think so.

7382. Suppose substances are preserved by smoking—such as kippered herrings and so forth?—If you buy a kipper you know what it means. “Kippered” is a label. All I am asking is a label. I do not want to be Quixotic in my demands.

7383. But we have to decide as to what is to be done, and the difficulty is are we to label smoked herrings, for instance? What is a smoked herring? What is the preservation due to?—It is due to the bodies in the smoke itself, I suppose.

7384. (Chairman.) Bodies in the smoke to which the herrings often are not exposed?—Quite so. A great deal of fraud goes on even in these matters.

7385. Are they not painted with pyroligneous acid?—I believe so. I believe there are all kinds of dodges.

7386. (Dr. Bulstrode.) Do you accept it that the preservation of those articles is due to traces of formic aldehyde?—I do not know.

7387. Supposing it were due to that, it would be necessary to label it, would it not?—Certainly.

7388. So with sugar. Would you label a thing which is preserved by sugar?—Yes, to be quite sure it was not preserved with saccharine or glycerine.

7389. Would you say so in the case of vinegar?—Yes, to be quite sure that it has not got sulphuric acid.

7390. You see no difficulties in carrying this labelling process out to its bitter end?—I do not.

7391. And so with milk and meat—you would label it all?—Certainly. I think it ought to be labelled. You ought to know when you are buying a frozen joint from an animal that was killed six months ago and when you are buying a really fresh joint from an animal that was fed on a farm at hand.

7392. Is it not a very relative matter? You buy a joint from an animal which was killed yesterday; that meat has been kept from decomposition by some means or other—either by cleanliness or by cold or by something else?—Yes.

7393. That will have to be labelled for you to carry out the thing to extremes, to be logical all through?—I do not think a man ought to be allowed to charge 11d. a pound for frozen mutton and sell it to you as fresh. I think that is a fraud, and personally I do not think it as good.

7394. You say in your synopsis “There can be no doubt that the fatality of infantile diseases (measles, whooping cough, tuberculosis, diarrhoea) is very largely dependent upon the state of the nutrition of the infant population.” Do you mean by fatality the number of deaths?—Yes.

7395. The mortality?—Yes.

7396. Do you think that the state of nutrition has anything to do with the receptivity to infection?—Yes, I think it has everything to do with it. The state of nutrition has everything to do with the vulnerability or immunity of the animal. Look at the way dysentery was spread and other diseases in Ladysmith, for instance. You had there a population which was by force of circumstances starved—deprived of food of various kinds; and when you get disease breaking out in a population of that kind it spreads, and is much more fatal, and it spreads much more rapidly than it does amongst a well-nourished population.

7397. You think there is a correspondence between the receptivity to infection and the state of health?—Clearly. I think there is no doubt about that.

7398. Would you prohibit all aniline dyes?—In food.

7399. Yes?—No, not if they were advertised; *caveat emptor*, I would not buy them.

7400. With regard to copper in peas, have you considered the question of its solubility in the form in which it is administered in peas? What evidence would you adduce to show that in the form in which it exists in peas it is soluble in the human system. Supposing it is not soluble, it does not matter much, does it?—I cannot conceive that it is not soluble in the human system. Copper has been detected in the animal body by chemists, I believe, and it must have got there somehow.

7401. It is not universally accepted at the present moment that it is soluble?—Is it not the fact?—I am asking you if you will kindly tell me—that copper has been found in the feathers of certain birds, and to such an extent that it has been detected chemically.

7402. (Dr. Tunnicliffe.) Yes, there is one instance in

which it has been found in the colouring matter of the feathers of a bird whose food was free from copper?—And the copper was there.

7403. Presumably?—It must have been soluble somehow? Sulphate of copper given in large quantities is an astringent, given in larger quantities it is an emetic, given in bigger quantities it will sometimes be a purge, and in larger quantities still it will be poisonous. I do not think it ought to be given.

7404. With regard to the question of copper in peas, would your view be modified when I tell you that it is impossible to eliminate copper from our diet?—Very well then, there is no occasion to add any.

7405. It is added to peas for the purpose of fixing the colour, of course?—Yes. It gives the pea a colour which never belongs to it. So I think. You can tell them at once, I think by the eye. It gives a colour which serves to me as a warning. When I get these peas at dinner I do not take them.

7406. With regard to the *a priori* probability of their being injurious to the consumer. Would the fact that it is impossible to eliminate copper from our diet in the same order of magnitude as is required to fix the colour of peas, in any way modify your view with regard to the probable effect?—Not a bit, because I cannot see any use in putting the copper in.

7407. That was not the point?—It would not modify my views.

7408. You still maintain that copper is injurious in any quantity whatever?—You are putting a question to me which cannot be answered. For instance, if you take a very minute quantity of lead it is not injurious. You might give me so many milligrammes of lead, and produce no result; but you know you cannot go on with it however small the quantity. I believe ultimately you produce lead-poisoning.

7409. The difference I suggest is, that we can eliminate lead from our diet, but we cannot eliminate copper; for instance, wheat contains copper, therefore the bread we eat contains copper?—If it is in the wheat, therefore we are getting quite enough copper in our diet without having any added to the peas. Presumably, if that is the case, copper may be of some necessity to our bodies, if it is always in our diet.

7410. In those circumstances do you think it would hurt us if we took 25 or 50 milligrammes more?—I cannot see any reason why it should be permitted without stating the fact; that is all. I only ask for the fact to be stated, that is all I plead for that the fact should be stated—“These peas contain so many milligrammes of copper.” I do not care what it is, but it ought to be stated.

7411. You think that after stating it then, it would be *caveat emptor*?—Certainly, you state what the article is and then *caveat emptor*.

7412. I understand what you mean is you do not object to preservatives *quod* preservatives?—Certainly not; preservatives which mean preserved food must always form a very important part of every national diet.

7413. But you regard the use of preservatives as being one of the factors which may deceive the consumer so that he gets stale food for fresh?—Quite so.

7414. And you think any undue proportion of stale food might increase scurvy?—Certainly.

7415. But you are not prepared to differentiate between the conditions in stale food that produce the scurvy?—No, certainly not.

7416. For instance, you cannot differentiate between frozen food, or between preserved food or sterilised food or pasteurised food, and so forth?—No, I am putting in a plea for our acknowledged ignorance upon that subject.

7417. You are a well-known authority on hygienic matters?—Yes.

7418. It has been stated here that if preservatives were prohibited in milk the middleman would cease to exist, and there would be some difficulty in the big companies reaching the very poorest classes of the community—the people who want at odd times a half-pennyworth of milk in short—have you any view to offer upon that subject?—The only view I have to offer upon that subject is this. Take the Colonies, where space is easily obtained. When you are founding a city, to have a certain amount of pasture ground and market

Dr. G. V.  
Poore, M.D.

14 May 1900.

Dr. G. V.  
Poore, M.D.  
14 May 1900.

garden ground is of such obvious advantage in every way that it ought to be provided for by any municipality when laying out a city in a new country. That ought to be thought of. When you get your fresh food too far from your population it is a disadvantage all round. Of course, we have got to accept the conditions as they are.

7419. The conditions amongst the poorer classes—and you know them practically—are very bad for the keeping of milk, even for twelve hours?—Very bad. What happens to pasteurised milk after it has been kept in their filthy larders and places goodness knows.

7420. Do you see in the fact that milk very often goes bad amongst those poor people, one reason for the

greatly increased use of conserved milks—tinned milks I mean by conserved milks?—Clearly I do see that, and it is a great thing to give people milk which is fairly wholesome; but I do draw a distinction between the milk as drawn direct from the breast of the animal and the milk which has been attended to in various ways, although I quite acknowledge, of course, the great advantage under our existing conditions of trying to find innocuous ways of preserving milk and all articles of diet.

7421. You think there is no absolute reason why a chemical method should not be an innocuous one?—No.

7422. No *a priori* reason that is?—No.

Sir L.  
Brunton.

Sir LAUDER BRUNTON, called; and Examined.

7423. (Chairman.) You are a Doctor of Medicine and Fellow of the Royal Society?—Yes.

7424. You appear here on behalf of the Royal College of Physicians?—Yes.

7425. Has your attention been directed to the use of chemical preservatives in food?—It has.

7426. To their prevalence and the possible consequences?—Yes.

7427. May I ask what general conclusions you have arrived at?—That it is almost impossible to prevent the use of preservatives, but that their use should be strictly regulated. If we do not use preservatives we run the risk of causing injury by food which is decomposing; but, on the other hand if we use preservatives in too large a quantity we may do harm through the preservatives themselves. Moreover it seems to me that by the unregulated use of preservatives we may possibly get a double danger—that from the drug itself which is used as a preservative, and that from the decomposing food which may, in spite of the addition of a certain quantity of the preservative still undergo change, and become dangerous to health.

7428. Taking as a type of perishable food the milk supply of a large town, do you think it possible to conduct it without the use of preservatives?—I do.

7429. Do you think it would be desirable to do so?—I think so.

7430. Is there the danger in the extensive use of preservatives at present known to be carried on, that in a delicate article like milk they may enable the vendor to dispense with such precautions as cleanliness?—There is.

7431. Have you formed any opinion as to the relative harmlessness or value of the different chemical preservatives?—I have formed an opinion, but the data upon which I have formed the opinion are so imperfect that I should prefer not to express any opinion. As will appear from the synopsis, I think that many more accurate data are required before an opinion of permanent value can be found. I have also given in the synopsis the way in which I think the data should be acquired.

7432. Would you kindly state it?—The data at present before us are imperfect. We are able to form opinions regarding the action of certain drugs from their administration either to animals or to men, but the length of time over which such experiments extend is too short to allow of a complete opinion being formed in regard to their action.

7433. Do I understand that you mean the cumulative action of such a drug would not be thoroughly ascertained?—The cumulative action, and possibly something more than the cumulative action, that is to say the continued action over a length of time, even though there should be no accumulation. To give an example of what I mean—if a man takes a little excess of sulphate of magnesia every morning, so as to cause rather too free purgation, there is no accumulation in the body of the sulphate of magnesia, but yet at the end of a year the continued excessive use of the drug has given rise to a condition of weakness which would not have been present but for this excessive use, and yet there has been no accumulation. I thus distinguish between the cumulative effect and a continued effect.

7434. To take the example of one common preservative—boracic acid; the amount of boracic acid which can be voided by the human subject in the course of 24 hours

is limited, is it not?—It is limited, but I do not know the limit.

7435. That is one of the elements of uncertainty?—Yes, that is an element of uncertainty.

7436. Although you might know the exact quantity being taken by a human being, it would be impossible to know whether there was any accumulation going on?—It would be difficult to know whether any accumulation was going on, and with the present data before us, it would be impossible to say whether any continuous, as distinguished from a cumulative, effect was being produced.

7437. What steps, then, would you recommend with a view to regulating the use of these chemical preservatives?—I should recommend that, in the words of the Select Committee on Food Products Adulteration in their summary of principal recommendations No. 19: "An authority should be constituted who should act as a court of reference upon scientific and other questions arising under the Acts, and who should be empowered at their discretion to prescribe standards and limits of the quality and purity of food." The data at present before such a board would be imperfect, and in order to procure such data, I think that it would be necessary to insist upon the presence, nature, and proportion of preservatives in each article of food being notified by label or otherwise. By such notification in case of any symptoms arising in a consumer, it could at once be ascertained what amount of any given preservative he had been taking in the course of a day, and over what time this consumption had extended. By then comparing a number of such cases, one would be able to make out definitely what effect had been produced by any given preservative in given quantity in consumers of a certain age, sex, and strength.

7438. You would then put in the power of the consumer the option of purchasing a fresh or a preserved article?—I should assuredly.

7439. I am not quite sure whether you have specified the exact constitution of the board which you think desirable?—I did not; there were various recommendations before the Committee, and I did not form a definite opinion except with regard to one point, and that was that as this Board would have to do much more with questions of pharmacology, medicine, and public health than with questions of chemistry, I consider that the medical profession were rather insufficiently represented upon it under the proposals that I have found in the previous evidence, and that the Royal College of Physicians in particular as being one of the most important public bodies in medicine should be represented upon the Board.

7440. (Professor Thorpe.) That Board was originally suggested, I understand, by analysts?—Yes, I believe so.

7441. With a view of prescribing standards or limits, as they are now called, with respect to what shall determine adulteration in certain articles of food, and also with a view of prescribing methods of analyses which should be used in common by analysts who have to report upon the fact of adulteration. You have rather enlarged the scope of the Board, or rather you have altogether changed its character in your suggestion?—No, I have not changed its character, but I have enlarged its scope. One would require to have upon it analysts who were thoroughly competent to understand the chemistry but you would also require to have upon it someone who understood not only the chemistry but the working of the proposed preservatives upon the human body.

Sir L.  
Brunton.

14 May 1900.

7442. Your suggested Board seems to me rather as sanctioning a vivisection experiment made by the public on themselves at their own cost?—No, I do not think so. There may be two opinions in regard to the utility of chicory in coffee; there are two very pronounced opinions, but I think that people should not be prevented from having chicory with their coffee, because I personally prefer the coffee without the chicory. I doubt very much if many of the preservatives in very small proportion would be any more harmful than the chicory, although I think that in excessive proportion they would be harmful.

7443. Then the object of your Board is practically to observe and to collect information respecting the action of preservatives?—The first process, of course, is to get definite information, and the next is to act upon it; at present we want the definite information. We can only act upon imperfect information, because we have not got the data. We can act to the best of our knowledge at present, limiting the quantity of preservatives in any article of diet, according to the best of our knowledge; but with the increased knowledge that we would acquire by observation we would then be able to issue definite rules, knowing then that we were right. At present the rules that we could issue would be such that we thought were right; later on they would be what we would know were right.

7444. You have already stated that in the case of milk you incline rather to the prohibition of preservatives?—I should be inclined, if possible, to carry on the milk trade without the addition of preservatives, and I think that it could possibly be done if the extension of the present methods of cooking were made absolutely compulsory. By the introduction of cooling, even into small shops, and by sterilising, it might be carried on without preservatives. But there also my information is to a certain extent defective, and I do not know how far it would be possible to carry on the sale of milk in the very poor districts of London without the addition of preservatives, nor whether by insisting upon the absence of preservatives entirely in milk one might not drive people simply to the use of preserved milk instead of the milk direct from the cow.

7445. Can you inform the Committee if there is any evidence that the use of sterilised milk is injurious to children—properly sterilised milk, and milk which is kept sterilised—I mean sterilised *per se*?—There, again, one falls upon the question of opinion versus fact; we have no sufficient data to form a definite opinion, but you will find various men taking the one side and others taking the other. I have heard it stated, apparently very definitely, that sterilised milk was exceedingly injurious to children. For my own part I do not think it is. The only point that I can see about it is that sterilised milk and boiled milk as a rule is not relished by children in the same way that fresh milk is, but as for definite knowledge upon the subject I have not got it.

7446. If it be the fact, as it has been represented to us, that at all events pasteurised milk can be obtained without any taint, or without any perceptible taste—is there any chemical change that you know of in the milk which would in any way render it injurious to children?—There is none that I know of, but I need not mention to Professor Thorpe, with his knowledge of organic chemistry, that very slight chemical changes in albuminous materials—changes utterly beyond the power of any chemist now to detect—convert an innocuous substance into a deadly poison. Between deadly poisons and their antidotes no chemist could detect the difference; I mean that the differences between serpent venom and non-poisonous albumoses are so slight that I do not suppose it is possible for any chemist to tell the difference between serpent venom and innocuous albumose. The only way in which the point would be settled would be by inoculation into a living animal.

7447. Is there any evidence that by raising milk, say, to the temperature of about 180 degrees Fahrenheit for a few minutes, there is any serious conversion of the albuminous matter in milk?—We have now got to the limit of our physiological knowledge. As you know perfectly well raising any fluid containing enzymes a very few degrees above a certain point would just make all the difference as to whether the enzymes remain active or not. Until we know more about the presence and action of enzymes in milk we cannot have any definite knowledge regarding the effect of sterilisation.

7448. I admit that it is thinkable; that it is conceivable; but I want to know whether from your own knowledge or observation any such change as the destruction of an enzyme, or the conversion of one form of proteid substance into another one—perhaps not a noxious form of

the proteid substance—has been observed to take place?—Not to my knowledge.\*

7449. (Dr. Bulstrode.) What would you regard as the least harmful method of preserving milk as far as your knowledge will allow you to state; I mean including sterilisation and the application of cold?—The application of cold is the best.

7450. You think that that would be the best means?—Yes.

7451. And the least harmful means of preserving milk?—The least harmful.

7452. Would you anticipate any bad results to milk from refrigeration, we will say?—No, none.

7453. You know of no facts which point in the direction that refrigerated milk may be harmful?—None.

7454. Is there a belief in the medical profession that refrigerated milk is harmful?—I do not think it is a general belief.

7455. Not so general perhaps as that sterilised milk is harmful?—I think not. But there I must guard myself for this reason, that although I have heard opinions expressed by individual members of the profession I have taken no census whatever of the profession to know the numbers.

7456. I rather gathered from your suggestions as to the constitution of this Board that you think this matter of preservatives an important one to the medical profession?—Assuredly.

7457. Of course you have thought of this matter in the light of drugs which are prescribed by medical men being used indiscriminately in certain foods?—Yes.

7458. Do you see in that a danger to proper medical treatment?—In the administration of certain of these preservatives there is a possible danger; I do not know how far it may be a certain danger. The possible danger is this: We know that certain drugs will counteract the effect of certain others, so that, for example, if you give an animal a lot of potash salts, and then administer barium the action of the barium is prevented—not entirely, but to a great extent.

7459. In that way the practice of the physician might be stultified?—Yes, but there again, as I say, we have not the data to work accurately upon.

7460. Let us take, for instance, a physician who goes into a hospital, and prescribes to a patient 10 or 15 grains of boracic acid three times a day; is it a matter of importance to the medical man, and to the patient, whether that patient may already be taking three times that amount?—Yes, I think it is.

7461. A serious matter?—I think so.

7462. And so with other drugs, such as salicylic acid and benzoic acid, and other preservatives?—Yes.

7463. There is one question I should like to get the advantage of your opinion upon now, and that is the contra-indications for the administration of certain drugs, more particularly borax and salicylic acid. If I may read you an extract from your work perhaps you would kindly give us your opinion upon it—this is in reference to borax: "It has been supposed to have a special action upon the uterus, and has been employed in amenorrhœa, dysmenorrhœa, and puerperal fever and convulsions. On account of its asserted power to increase the uterine contraction it ought either to be avoided or employed with great care during pregnancy." If that statement is the fact, is there not a danger that a very large number of child-bearing women may be at this time taking something which, according to this statement, is contra-indicated?—There is a certain danger of that.

7464. Then with regard to the use of salicylic acid, may I just read you this: "Sometimes, however, the salicyl compounds so irritate the kidney as to cause albuminuria, and even hæmaturia; and they must be used with great caution when given for this or other purposes if renal or hepatic disease be present, and in aged persons inasmuch as under their influence there is an increase of the amount of uric acid waste, and they are apparently not diuretic. The salicylates are believed by some authorities to be harmful in gout." Assuming that again to be true, do you see in that an objection to the indiscriminate use of salicylic acid?—To the indiscriminate use certainly; and

\*This answer refers to the effect of raising milk to 180 degrees Fahr. for a few minutes and not to the effect of prolonged boiling, which causes coagulation of some of the albuminous constituents with the formation of a scum on the surface.—L. B.

Sir J.  
Bruntton.

14 May 1900.

that I think affords a very strong proof of the correctness of my suggestion that preservatives should not be allowed to be used without the person who is using them knowing that he was taking them, because in the great majority of cases salicylic acid will not produce those symptoms, but there are certain individuals who might be thus affected. If salicylic acid is allowed to be used without its use being notified to the consumer, he may be suffering from those symptoms, while he himself and his medical man are totally in the dark in regard to the cause of the symptoms, whereas if it is notified that the milk or other food which he is taking contains a certain proportion of salicylic acid the attention of the medical man would probably be at once directed to the possibility of salicylic acid having been the cause of the symptoms.

7465. Do you think it eminently desirable that the milk supply to all hospitals should be examined for preservatives?—Yes, I do.

7466. (*Dr. Tunncliffe.*) I take it what you mean in regard to this Board is that this present Committee is hardly in a position to get sufficient data to form an opinion upon so important a matter?—That is so.

7467. And that, even supposing such a Board were appointed, the appointment of that Board might lead eventually to the prohibition of preservatives?—It might.

7468. Would you give to the Committee your opinion with regard to the probable injuriousness of very small doses of copper, as an instance 25 to 50 milligrammes twice a week?—That question, I believe, has been very thoroughly worked out; the presence of a minute dose of copper is quite innocuous.

7469. (*Chairman.*) That being your opinion on the use of copper, would you object to its employment as a colouring matter without declaration?—Certainly, because although the presence of that copper in that proportion might be innocuous, I think that the principle of allowing

anything of the sort to be used without declaration is most objectionable. But it has been said, I believe, as an objection to the declaration, that it would interfere with trade, and that it would interfere with various things being sold. It seems to me that it would not do so in the very least; all that would be necessary would be that each article should bear a label stating that it contains such and such a preservative in the proportion licensed or approved of by the Board or Committee which is proposed to be constituted; people would then take the article of food readily enough, and there would be no interference with the trade, and there would be a great security for the consumer.

7470. Is there not a practical difficulty in declaring the proportion of the drug or colouring matter used, inasmuch as a quantitative analysis is a troublesome thing to undertake, and also that there may be a different proportion of the substance in one part of the consignment to another?—There ought not to be.

7471. Is that not very much the character of the substance we have mentioned last, sulphate of copper; is it not apt to collect more in one portion of a parcel than in another?—It may; but that could easily be stopped in this way: if it were found to have collected in a larger proportion in one part than in the other, and exceeded in one part the proportion allowed by the Board or Committee, the manufacturer should be held liable. He ought to have taken greater care to distribute his copper throughout the peas.

7472. We are talking of a practical difficulty; take our friend opposite, Fortnum and Mason, he does not manufacture, he imports from abroad; would you hold him responsible for an excess of copper in a bottle of peas?—Certainly; he would then come back upon the manufacturer, and the manufacturer next time would take good care that the peas were up to sample.

Mr. F.  
Womack.

Mr. FREDERICK WOMACK, called; and Examined.

7473. (*Chairman.*) You are Bachelor of Science, Bachelor of Medicine, and Lecturer on Physics at St. Bartholomew's Hospital and Bedford College, I think?—Yes.

7474. You have directed some attention to the effects of some of the modern chemical preservatives upon the consumer?—Personally I have not had my attention directed to very many cases on my own account—I have come across them rather by way of accident, but I know of a few instances where preservatives in milk particularly have caused some little derangement.

7475. Could you describe them to the Committee?—Two instances occurred in a family living at Ealing, where the preservative was boracic acid added to milk. In both father and daughter there was a considerable amount of digestive interference set up caused by the presence of a comparatively small amount of boracic acid in the milk.

7476. Was it undoubtedly traced to that?—I think it was undoubtedly that, because as soon as they changed their supply the symptoms practically disappeared. I myself tested the milk, and found that boracic acid was present in it.

7477. Do you know in what proportion the boracic acid was present?—No, I am afraid I cannot tell you now; it was a small quantity only.

7478. Is the opinion you have formed unfavourable to the use of these preservatives?—No, I cannot say personally that it is in general, though there are just a few cases which I have lighted on of that character where they seem to have been the cause of some derangement. I cannot say that I have any strong feeling against the use of boracic acid or some other preservatives.

7479. Should it be put under any regulation?—I think if possible it would certainly be desirable to have regulations governing the use of any such bodies.

7480. (*Dr. Bulstrode.*) As a physician, do you see any objection to the indiscriminate use of drugs which are used in practice?—I am afraid I ought not to accept your first suggestion "as a physician," because I am not one. I have only qualified as a physician, and I have never done any practising in medicine. I have devoted myself to physical science entirely.

7481. Lecturer on physics is your correct designation?—Yes.

7482. In what capacity may we ask your opinion?—I

take it that I was chosen by the Committee of the School to attend a meeting of the Committee here. I cannot tell the reason why they made the selection. Possibly it was because I am associated with the toxicological examinations for the County Council; that is the only chemical work that latterly I have kept in touch with.

7483. Can you tell us anything as to the action of formalin in milk?—Physiologically?

7484. Yes?—No, I am afraid I cannot give you anything from my own experience.

7485. Do you see any danger in the indiscriminate use of a substance like formalin?—My own personal opinion is that it would be highly objectionable.

7486. For what reasons?—I think it would interfere with the formation of enzymes and the bacteria which are associated with the proper digestion of milk and other foods. I think if it acts antiseptically in one direction it probably will equally act as a bactericide in others.

7487. Looking at the varying effects of different antiseptics and disinfectants, does it necessarily follow that the destruction of certain bacteria means the destruction of all bacteria?—No, I think not.

7488. It would be possible that any given substance might act as an absolute disinfectant to certain bacteria and might have no detectable effect upon others, would it not?—Yes, certainly, I think so.

7489. Do you think a substance like formalin might act upon the secreting powers of the cells?—I should think it certainly might if it were present in anything more than a minute quantity.

7490. Do you know anything as to the hardening effect of formalin upon the animal tissues?—Yes, certainly. Of course, I am speaking now generally; it would depend very much upon the proportion a person used as a preservative.

7491. You think if it is used at all it should be limited?—Certainly.

7492. You speak in your proof of the "ill-effects on digestion from inhibition of large doses of boracic acid given medicinally," and you refer there to Dr. Church. What are we to understand by that?—Dr. Church particularly gave me an instance of cases in the wards where he had had occasion to give boracic acid in large quantity, and where he had found that it caused considerable

derangement of the digestive processes. He implied in his letter to me, which I shall be very happy to show to the Committee if they care to see it, that in small quantities he has not observed any injurious effect.

7493. (*Chairman.*) You appear on behalf of St. Bartholomew's Hospital?—Yes.

7494. (*Dr. Bulstrode.*) Could you give us the amount in the cases in which it produces bad results?—Dr. Church said it was given in 15 grain doses.

7495. To an adult?—He does not definitely say, but there is no doubt that he implies an adult.

7496. Was it an adult in health, or what would it be given for?—That he did not say.

7497. In how many cases did this occur?—I will read the letter. The letter is dated the 5th of May, and he says: "I have nothing to communicate with regard to boracic acid or formaldehyde. The former I have not infrequently used as a medicine internally, and on one or two occasions large quantities have produced unpleasant symptoms, upsetting the digestion, and causing distate for food, but the quantities were far in excess of anything that would be suggested as a food preservative. If I remember rightly the symptoms resulted from 15 grain doses every four or six hours."

7498. Are you aware that as much as 80 grains of boracic acid have been found in a pint of milk?—No, certainly not.

7499. That would rather modify Dr. Church's opinion, would it not?—Yes.

7500. Then you mention the objection to formalin in milk and butter in connection with the names of Mr. Lockwood, Mr. Vernon, and the majority of the medical staff; would you just amplify that?—In most of the cases the letters I have received merely state that they have not any definite evidence to proffer to the Committee, but that they have themselves a feeling of objection to the presence of these bodies in either milk or butter.

7501. But they furnish no evidence in support of their views?—No, they gave me no clinical evidence at all.

7502. You also state on your proof that there is no clinical evidence of the effects of small doses, and you quote Dr. Champneys, Mr. Bruce Clarke, and the majority of the staff; would you explain exactly what that points to?—They merely stated in their letters that they could not give me any definitive cases that had come under their own observation in the wards as to any ill results following from the presence of small doses of preservatives.

7503. Did they tell you what good results had followed the effects of such small doses?—No.

7504. From the evidence which you put before us may we gather that the staff referred to are rather hostile to the use of preservatives?—Yes, that was the general feeling, undoubtedly.

7505. Was it also the feeling that there was an objection to the use of milk preserved by drugs; in hospital practice many of those things such as boracic acid and salicylic acid are drugs prescribed to patients; did they feel that their indiscriminate presence in a food like milk ought to be regulated?—That was certainly the general feeling; one or two wrote quite strongly from that point of view.

7506. Could you give us an instance?—Mr. Lockwood writes to that effect. He says: "I should have thought that the authorities would know their business better than not to have the supplies properly looked after." He is astonished that milk or butter should be sold containing any trace of preservatives at all.

7507. (*Professor Thorpe.*) That is not so much regula-

tion as absolute prohibition?—It is absolute prohibition from his point of view, certainly.

7508. (*Dr. Bulstrode.*) Are there any other letters which you think the Committee would be glad to have on their minutes?—I am afraid they are all of that negative character; they are not prepared to state clinical evidence, but they for the most part state that they feel there is an objection to the presence of those bodies in food stuffs.

7509. (*Dr. Tunncliffe.*) Have you got any opinions to offer with regard to the presence of colouring matters either on your own part or on the part of St. Bartholomew's?—No, I have not anything to offer at all, I am afraid, about that.

7510. For instance, would you like to say anything upon the subject of the presence of copper in peas?—My own personal view is that the presence of copper in any quantity whatever is liable to be highly deleterious.

7511. Irrespective of the way in which copper is present, for instance, as an insoluble compound in the case of the pea?—Yes. I am not prepared to modify my opinion because of the insolubility.

7512. If it can be shown that a large amount of the quantity ingested was eliminated in the faeces, would you still hold the opinion that it might cause an ill effect?—Yes, unless it can be shown that it was wholly eliminated, I should object to its being used.

7513. The Committee have heard a good deal from the witnesses with regard to the hardening power of formic aldehyde upon proteid material; could you give the Committee any information with regard to the characteristics of the actual compound formed between formic aldehyde and proteid; I mean as to the molecular proportion?—I am afraid I cannot from my own knowledge.

7514. It is the fact, is it not, that in the case of these hardening instances the formic aldehyde is used in a very much larger proportion than in the case of its employment as a preservative?—Yes, certainly.

7515. Do you know about how much is the average quantity of formic aldehyde used to harden a proteid?—No, I am afraid I have not actually personally used it. I only know about it second hand as to its employment as a hardening agent.

7516. Do you think it follows *a priori*, that because formic aldehyde is a hardening agent that the compound formed with proteids by it will be indigestible?—You have no *a posteriori* evidence to offer, so I ask you for your *a priori* view?—Yes, I think it does.

7517. Would you expect that formic aldehyde would render milk more indigestible by virtue of the fact that it would form with casein, a relatively indigestible compound?—Yes.

7518. For *a priori* reasons?—Yes.

7519. Therefore you would object to its use in any quantity whatever in milk?—I am not prepared perhaps to go quite so far as that, but I certainly think its use should be very largely under restriction.

7520. How would you purpose to restrict its use?—I am afraid that there I cannot give you a very definite answer on account of the difficulty of determining the quantity of it present.

7521. The same difficulty would apply to boracic acid, would it not?—Yes.

7522. And to salicylic acid?—Yes.

7523. As far as you have been able to collect actual clinical evidence, it is what you might call very indecisive upon this question?—Yes.

7524. In fact no evil results, or practically none, have been noticed at a large hospital?—No.

Professor W. D. HALLIBURTON, M.D., F.R.S., etc., called; and Examined.

7525. (*Chairman.*) You are Professor of Physiology in King's College, London, and Fellow of the Royal College of Physicians?—Yes.

7526. I understand your attention has been directed to some of the effects of modern chemical preservatives?—Yes. May I say first that I come here at the request of the Royal College of Surgeons. I have been nominated with Professor Starling; I think he gave evidence last week. I sent in, I am afraid, a rather lengthy synopsis of some of the observations and experiments that I have made.

3017.

7527. I have it, and I will let you take your own way through it?—May I just, as it were, summarise, and that will, of course, leave you, as you like, at your leisure to go into the details that I have presented.

7528. Would you, please?—I would say at the outset that the kind of evidence that I have to offer is not very largely clinical. The amount of medical practice which I have seen is limited. Very soon after my student days I took to physiological work, and I have remained at that more or less ever since; so that the actual observations that I have to make are in the nature of physiological ex-

Mr. F.  
Womack.

14 May 1900.

Prof. W. D.  
Halliburton,  
M.D., F.R.S.,  
etc.

*Prof. W. D. Halliburton,*  
M.D., F.R.S.,  
etc.  
14 May 1900.

periments, and deal principally with the two chief substances that you have under investigation, as I understand—compounds of boron and formaldehyde. On general principles one would object to the continuous use of antiseptics. The substance which would destroy the life of micro-organisms could not be expected to be beneficial to the life of a higher organism; it would be largely a matter of dose; I mean to say the same dose that would kill a bacterium would not necessarily kill a man, but still it would be hostile to the protoplasmic actions that constitute the life even of a high animal like man.

7529. It is not inseparable from antiseptics that they should be injurious to digestion. I think—it does not follow?—You are thinking of such a substance as common salt perhaps?

7530. Yes?—That is a normal constituent of the body. There have been cases recorded where the immoderate use even of such a normal article of diet has been injurious. It is very largely a matter of degree all through. Of course, a typical instance is in the use of sulphur. If a man were to stay in a room while it is being fumigated by sulphur he, as well as the micro-organisms, would suffer. Even in such a simple process as the process of cooking—the commonest method of destroying micro-organisms—there are some disadvantages. These are disadvantages which the most of us can cope with, but still to a person with feeble digestion, over-cooked meat, and hard-boiled eggs are almost proverbially indigestible. Of course, one always has to weigh in the case of cooking the disadvantages against the advantages; and so with antiseptics it is always a question which is the more advantageous to put up with, the products of putrefaction or the antiseptic which has been used to prevent putrefaction. So far as I can say, on the whole, if it were possible it would be better to prohibit the admixture of foods and foreign substances, and substitute for it the wholesale use of a method of cold storage and transport.

7531. Cold storage has a deteriorating effect upon animal substances, has it not—for instance, meat?—You mean to say that New Zealand mutton is not so nice.

7532. That is an extreme instance. But if you put a partridge into cold storage in December and took it out in June you will not find it so palatable?—No; a partridge is an instance the other way, because that is a form of food which we have been taught to like in a somewhat putrid condition. The flavour of a partridge is by epicures, I suppose, not considered right unless a certain amount of putrefaction has taken place. In the case of milk coming from the country there could not be anything like the length of time as there is in meat, coming from New Zealand, and I should say, under those circumstances, there could be no deteriorating effect produced. One reason, I fancy, of the difference of opinion that has been so freely expressed with regard to the use of antiseptics is the idiosyncrasy of individuals. Some people are so more readily susceptible to the use of certain drugs—take salicylic acid, for instance—than others are. If the Committee do not see their way to recommend the absolute prohibition of antiseptic materials I would suggest that where they are used a label or something of that sort should indicate what has been used, so that people who are particularly susceptible to, say, borax or salicylic acid, should know what there is in this can of milk, or what there is in that cart load of meat, so that they may avoid it.

7533. People should no longer be permitted to sell as fresh milk containing a preservative, taking milk as a type?—Yes, that is so, and that if milk has a preservative in it it should be so indicated. I do not think I need dwell upon the paragraphs under the head of “salicylic acid,” “benzoic acid,” “carbolic acid and corrosive sublimate,” or “metallic admixture.” They are merely brief statements mainly gathered from others.

7534. What do you refer to under that head of “metallic admixtures”?—That relates to copper, particularly.

7535. For colouring purposes?—Yes. And not only that—there is a good deal of copper and tin, too, in canned foods, which are not necessarily coloured by the copper.

7536. Sometimes to a dangerous extent, is it not?—Yes, there have been some cases recorded by German writers. I have noted down the name of one who has done a great deal of work at it—K. B. Lehmann. He states that in an ordinary German diet there are about 20 milligrammes of copper daily, and if preserves are much used it may rise to 300 milligrammes a day. He considers more than 120 milligrammes in a day is harmful.

7537. The presence of this copper is accidental, not intentional?—Yes.

7538. It arises from an accidental effect in the mechanism of preservation?—Yes. I am afraid I do not know very much about colouring matter added to milk except in the case of one child—the baby of a friend of mine—who suffered from dyspepsia, and it disappeared when their milkman was persuaded to give them uncoloured milk.

7539. What did he use?—I do not know what the pigment was. I could not ascertain. As a general principle, I should say it is best to avoid the use of artificial dyes, which are quite unnecessary, and the public should be taught that rich milk and rich butter need not necessarily have a bright yellowy tint.

7540. You are aware how arbitrary is the taste of the public in these matters?—Yes, I know.

7541. Then, as to boric acid, you have made extensive experiments?—With borax and borates I have made a fair number of experiments. In the introduction I allude to what is known as “borism.” The eruption occurs on the skin of certain individuals as the result of the use of either boric acid or borax. There have been other cases recorded—although here again I cannot speak personally—in which dyspeptic troubles have arisen. There have been a fair number of experiments performed upon animals.

7542. Does it amount to a strong opinion that you have that the use of borax as a preservative in food should be notified?—Yes.

7543. You think it is important to the public generally?—Yes, to the public generally; especially borax more so than boric acid. Borax is much more readily soluble, and they get much more of it.

7544. Boric acid is the commoner preservative, is it not?—I am not so sure. I think very largely a mixture is used that is called glacialin—a mixture of borax and boric acid. In animals the chief advantage—if one may put it so—of the poison is that it is not cumulative; it does not accumulate in the body, but it is rapidly eliminated by the urine.

7545. Up to a certain maximum?—Yes. I should say that the continual passage of a foreign substance through the kidney cells cannot be likely to do them any good. Some years ago Professor Allen, of Birmingham, formerly Professor of Physiology at the Mason College there, drew my attention to cases of malnutrition in infants fed on milk treated with borax. On examining the matter Professor Allen found that borax prevents the normal action of rennet. In milk digestion there are two ferments that come into play; there is the curdling action of rennet, which acts first of all, and then there is the subsequent solvent action of pepsin. It appears to be necessary for the proper peptonisation by means of pepsin that there should be this preliminary breaking down of the proteid molecule in the milk, which is evidenced by the formation of a curd. I have repeated those experiments, and found that Professor Allen is perfectly right. I could not find that there was any hindering influence when boric acid was employed, but I found that there was a very distinct hindering influence when even minute doses of borax were used in the milk. For instance, in one experiment I found that one decigramme of borax added to 100 cubic centimetres of milk entirely prevented the curdling action of rennet.

7546. For an indefinite time?—It was watched for 24 hours, and I threw it away then. That is an instance of a fair number of experiments that I have done. The milk kept good all the time. In a specimen to which a similar quantity of boric acid had been added the milk did not keep good.

7547. What were the conditions of temperature?—The temperature of the body 37 degrees Centigrade, 99 degrees Fahrenheit.

7548. The inference, then, is that the digestibility of the milk was seriously interfered with?—Yes. I should say, to summarise, that of the two—boric acid and borax—borax is the more efficient antiseptic, and it is also more harmful to the soluble enzymes which act upon the milk during digestion. With regard to formaldehyde, I should say that that substance should be absolutely prohibited. It is an extremely efficient antiseptic—a marvellous antiseptic—but it acts also in quite small doses on the unorganised ferments, or the enzymes, and I have in my synopsis presented experiments which prove this with regard to the gastric digestion of albumen, the pancreatic digestion of albumen, the pancreatic action upon starch, and the action of the rennet upon milk. I have

taken those as four typical digestive enzymes. The amount of formaldehyde which produces deleterious effects upon digestion is surprisingly small. May I call your attention in particular to the experiments upon the pancreatic juice, which is headed "Influence of Formaldehyde on the Pancreatic Digestion of Proteid." The pancreatic juice is the most potent of all our digestive juices. Some fresh fibrin was taken and submitted—these were all equal weighed quantities—to the action of artificial pancreatic juice, and digestion was completed—that is to say, all solid fragments had disappeared—in thirty minutes. The fibrin, which had been placed previously in a solution containing five parts in 10,000 of formaldehyde, took more than three times as long to digest; and with the fibrin which had been placed in double that strength one part in 1,000, or in a strength greater than that, there was no trace of digestion even at the end of twenty-four hours. The hardening influence is remarkable also. Even these minute doses of five parts in 10,000 and one part in 1,000 produce extreme hardening, and I imagine that some of the lack of digestion is due to that as well as to the influence which the drug has upon the ferments contained in the digestive juices.

7549. (*Professor Thorpe.*) You say in your proof that you incline to the belief that certain obscure conditions of ill-health might sometimes be traced to the use of antiseptics. Would you kindly tell the Committee more in detail upon what you base that opinion?—Upon the cases I see recorded from time to time in the medical journals. I believe Dr. Anderson gave evidence here within the last few days; he has from time to time in the *Lancet* described cases in which dyspeptic troubles which he has noticed in his patients have passed off after having ceased the use of food containing borax. As I said before, the number of actual patients that I see myself is extremely limited, as I am not in actual medical practice.

7550. I gather from what you have told the Committee that you would prohibit the use of formaldehyde altogether?—Yes.

7551. You would equally prohibit the use of salicylic acid?—Yes. Salicylic acid I should consider an extremely dangerous drug.

7552. Even more dangerous than formaldehyde?—It is dangerous in a different way. It is not such an extremely hardening agent, and apparently it is not so hostile to the influence of enzymes in the alimentary canal; but its danger arises from the mental symptoms, which in some people even small doses will give rise to—excitement, delirium—maniacal symptoms even in some cases.

7553. Even in such doses as are likely to be found by using it as an antiseptic in food?—I should hardly expect to get maniacal excitement in such cases, but I should anticipate that even such small doses as are found in food would produce the nervous and mental excitement which are a mild degree of this mania.

7554. Have you anything to tell the Committee with respect to the use of colouring matters—to begin with copper; do you consider that copper may be introduced, for example, into peas without any hurtful effect?—It all depends on the quantity.

7555. Would you, in fact, palliate the use of copper in peas—that is what I rather want to get at—would you condone it?—No, I should condemn it.

7556. On what grounds would you condemn it?—On general principles, first that it is a foreign substance; that, even although a considerable quantity may pass into the fæces, the acid of the gastric juice may cause a certain amount of solution, and therefore a passage into the cells of the body of the copper; and that foreign substances, especially metallic admixtures, become cumulative, and are not readily eliminated. Of course, I know that in some animals there are normal copper-containing substances, but that is not so for mammalian animals—there is no normal copper-containing constituent of the body with them. In crabs and lobsters and in the plant-eating birds there are substances which normally contain copper. The blue pigment of the crab is a copper-containing substance, and the red colour of those birds, the touracans, is a copper-containing substance; but those are entirely exceptional things in the whole animal kingdom. There is no copper-containing substance normally in the human body.

7557. I gather you would be inclined to prohibit the use of copper in a substance like peas or similar vegetables?—Yes, even although a certain number of people

may eat them without experiencing any harm, just as we are all breathing every day tubercle bacilli and not getting tubercle.

7558. You say you are aware of Liebreich's pamphlet on the action of borax?—Yes.

7559. Have you any opinion or remarks to make upon that that you would like to bring to the notice of the Committee?—Not further than what I have put in my own synopsis. It appears to me to be rather the position of an advocate that he takes than putting down the thing from the absolutely impartial point of view.

7560. It struck you on reading the pamphlet that the evidence was rather biassed?—Yes, I thought it was rather biassed.

7561. You say in your synopsis that Professor Liebreich in a letter to the *British Medical Journal* has practically admitted that his writing was from the point of view of an expert retained for the defence?—It struck me so from reading the letter.

7562. (*Dr. Bulstrode.*) With regard to those experiments of Liebreich, could you tell the Committee in what manner you thought they exhibited evidences of bias?—I do not know that I am prepared to stand an examination upon the details of the paper.

7563. Could you criticise destructively for our benefit any of the experiments which he made?—It was more in his general conclusions that it struck me where the bias came in, saying that the substance was absolutely harmless, in spite of the fact that he admits the occasional occurrence of borism.

7564. In large doses?—Yes, he mentions large doses. I do not think he has taken sufficient notice of the cases that have been recorded where much smaller doses have been able to produce the effects.

7565. Do you think one can deduce much as to what may happen in the human economy from that which takes place in that of a dog?—With certain allowances, yes; but I should say that on the whole the dog was a more resistant animal.

7566. More resistant?—Yes, it has, so far as the alimentary canal is concerned, a much stronger series of juices; it has been shown in dogs that you can give them quantities of corrosive sublimate and of iodoform, and completely sterilise their alimentary canal—quantities which it would be absolutely fatal to give to a man.

7567. Do you think it is fair to argue on what might happen to a puppy from that which happens to an adult dog?—Do you mean if I did experiments on a puppy should I apply them to the adult dog?

7568. Would you infer that that which happened in a dog would happen to a puppy?—The puppy takes more milk. It has a different kind of food to the adult dog, but, on the whole, the metabolic processes in the young animal and in the old one are much the same.

7569. Do you know anything of the experiments of Dr. Annett and Professor Boyce, of Liverpool, in reference to kittens?—No, I do not know those.

7570. Do you know they experimented with boric acid?—That had escaped me; I did not know that.

7571. With regard to the effects of salicylic acid in producing a certain disturbance, do you know if that has decreased lately owing to pure salicylic acid being used?—That I do not know; I see very little hospital practice now.

7572. May we take it, then, that in your view you are absolutely opposed to the use of formalin?—Yes.

7573. And that with regard to the other preservatives, if they were labelled that would meet your objection; is that your position generally?—No, I feel that the ideal condition of things would be to prohibit them all.

7575. All preservatives?—All preservatives.

7575. Even salt?—No; I am not speaking of substances which are normal constituents of the body.

7576. Would you prohibit nitrate of potash, too?—Yes. One knows, even from smoking cigarettes, that nitrate of potash is not absolutely harmless.

7577. You would prohibit all preservatives which are not discovered in the normal body?—Yes.

7578. Would that not be rather difficult to carry out—I mean to classify properly?—That is what I say. It is difficult, but still it is the ideal condition of things, and as much as possible, therefore, their use should be prohibited, and cold storage or cold transport substituted

*Prof. W. D. Halliburton*

for it. But of the preservatives I would say that boracic acid is the least harmful and probably the least efficient.  
7579. Less harmful than salt?—I am not including salt. I am speaking only of foreign admixtures. Salt is a normal constituent of food, and a normal constituent of the body.

7580. Could you tell the Committee anything as to whether the use of sterilised milk is prejudicial, or is likely to be prejudicial, to the health of an infant taking it?—I have only heard that such statements have been made, and they have astonished me.

7581. As a physiologist can you say anything upon that?—As a physiologist they have astonished me. Of course, a good many astonishing things do occur in nature, so it may be true; but on *a priori* grounds it seems to me remarkable and inexplicable.

7582. You know of nothing to support the view?—I know of nothing to support that view.

7583. (Dr. Tunncliffe.) Your experiments with formic aldehyde were made, of course, technically *in vitro*?—Yes.

7584. I take it from the general results you would expect, therefore, that, supposing it were possible to administer formic aldehyde *in vivo* the quantity of undigested matter, especially the nitrogenous matter in the faeces, would be largely increased?—That would be so.

7585. That would confirm your experiments and your experiments would confirm it?—Yes; but I have not done any experiments *in vivo*.

7586. The proportions used by you in the case of the digestion of fibrin were rather strong, were they not? It comes out to 1 in 2,000 of formaldehyde. That is hardly analogous, is it, to the quantity of formaldehyde used in milk, for instance?—Yes. A drop of 40 per cent. per fluid ounce comes out to more than that. A "few drops" is what one usually hears prescribed as commonly used.

7587. That is what I should like to know—whether you have any definite evidence for the statement that you make with regard to the quantity used?—Yes, I had it worked out. I cannot do mental arithmetic here, I am afraid, but those weaker figures come out distinctly within the possible limits that are used commercially.

7588. Therefore you would say that commercial formaldehyde has been used within your knowledge in the proportion of 1 to 2,000?—Yes.

7589. Did you ever taste milk formalised in the proportion of 1 to 2,000?—I do not know that I should know that the milk had been formalised, did I ever taste it, do you say?

7590. I believe it would taste?—No.

7591. Are you aware of the fact that Foster has done some metabolic experiments with boracic acid which were published in the "Berichte des Deutschen Chemisches Gesellschaft," five years ago, and also in the "Archive d'Hygiène"? Are you aware of those experiments?—Yes. I am not prepared to stand an examination on them, but I read them, and I know something about them.

7592. Would the remarks which you made, and which I think are quite justified, with regard to Liebreich's paper, apply to Chittenden's work, which you know, I presume?—Yes, I know Chittenden, too.

7593. Would you have any hesitation in saying that Chittenden's work is from the best and highest scientific standpoint?—Yes. He is one of the first men in the physiological world.

7594. But his results are more or less the same. Chittenden shows that in certain quantities boric acid is innocuous, so far as dogs are concerned?—Yes, so far as dogs are concerned.

7595. You feel very strongly upon the subject of copper in peas, I gather?—No, I do not. It is not a question to which I have devoted very much attention, and the opinion that I expressed in answer to Professor Thorpe was more the result of the application of general principles.

7596. (Chairman.) Ethics?—Yes. It was more on the spur of the moment that I answered Professor Thorpe. It is not a question that I have devoted any experimental attention to.

7597. (Dr. Tunncliffe.) The fact of the copper being present anyhow, and unavoidably present to a certain extent in our diet, would influence you surely with regard to your views as to copper being a foreign substance?—I do not quite follow you.

7598. The chances are that every man existing at the present moment has copper in his body—whether he takes coppered peas or not?—Yes.

7599. Although, perhaps, it is, strictly speaking, foreign to the animal body, since we cannot separate it from the animal body, do you think its foreignness is somewhat modified by that fact?—Yes. It goes on accumulating in the body, and there is no doubt that a large dose does produce effects which are bad. That, of course, is incontrovertible, is it not? One would imagine that the accumulation of this substance would similarly tend to produce effects of malnutrition.

7600. And would necessarily be more marked the older we are?—Yes.

7601. (Professor Thorpe.) You have given a considerable amount of attention to the chemistry of proteid bodies?—Yes.

7602. Can you tell the Committee whether our knowledge of the proteid substances present in milk is pretty accurate? Should you say that there are a number of indeterminate and indefinite things in milk of which we have no knowledge?—No; I should say that milk is about as well worked out a specimen of a proteid fluid as there is.

7603. That is to say, you think the chemistry of milk is pretty well understood?—We do not understand what a proteid is yet. With the exception of that fundamental point I should say that milk and blood are the two things that we know most about.

7604. When you say we do not understand what a proteid is do you mean by that that we do not understand the chemical analogies and relationships of the proteid, or what do you mean?—I mean we do not understand the way in which the atoms are built into the molecule.

7605. But we understand the proteid as a fairly distinct entity, capable of being isolated and characterised?—Yes. I mean to say you cannot make it in the laboratory. You do not know the way in which its atoms are pieced together; we do not know the constitutional formula.

7606. We do not know the molecular weight?—We do not.

7607. And, of course, of thousands of other substances you would say the same?—Yes.

7608. Still, it is a distinct entity?—Yes. Proteids are well characterised substances, and I should say that our knowledge of the proteids of milk are about as complete as our knowledge of the proteids of anything.

7609. Speaking from that knowledge, do you see any reason to suppose that the operation of pasteurisation, which consists in raising the milk, and, of course, the proteids along with it, to a temperature of about, we will say, 180 degrees Fahrenheit at most for a comparatively short time—five, six, or ten minutes, it may be—do you see any reason to suppose that that fundamentally alters the nature of the proteid? Is it likely?—Yes, it is likely to.

7610. You think it is likely to?—Yes.

7611. In what direction is it likely to fundamentally alter it?—It would produce a greater difficulty in digesting it. I mean to say it would become more insoluble.

7612. Is that alteration of a physical or a chemical character? Do you mean that it tends to coagulate—is that it? It does not actually coagulate.

7613. It tends to coagulate?—It tends to become more insoluble, and I imagine, too, that in the proteids of milk, where you have phosphorus either in an organic or inorganic form loosely combined with it, there would be bound to be an alteration in the relations of the proteid to the phosphorus containing constituents.

7614. Do you mean something in the nature of lecithin or something of that kind in the milk?—Something in the nature of nuclein—some substance of which the nuclei of cells are composed—and there are also inorganic phosphates which appear to be more or less loosely linked to the proteid matter, and that relationship of inorganic to organic substances is altered by boiling.

7615. How is it altered? Is the stuff, for example, in the yolk of an egg broken up by something analogous to hydrolysis, or what; what happens to this complex thing by the action of heat—what is your idea?—I imagine that it is of the nature of hydrolysis, although, of course, that again is very difficult to say without knowing the molecular constitution of the proteid material.

7616. What I am really driving at is this, to try and think out what change can possibly take place in pasteurised milk, which would in any way modify its effect as food, and possibly bring about some toxic action? Is there anything, speaking from your chemical knowledge, of the nature of this—anything that is *a priori* reasonable to expect would occur in milk of this nature which has been boiled?—The splitting off of a toxin from the proteids?

7617. Yes?—I should say it is extremely improbable; it must be a very mild toxin at any rate.

7618. Of course, we must have used boiled milk from time immemorial, year in and year out?—It is a slow poison if it is a poison at all.

7619. Rice puddings are a well recognised form of nursery diet for children?—Yes.

7620. And mothers have for a long period given children a diet consisting of various forms of boiled milk, and

this has hitherto been considered to be the very best form of simple food that you could give to children?—Yes.

7621. Would you say, therefore, it is reasonable to expect that if there be any specific toxic action arising from the change taking place in the albuminoids of milk it ought to have been observed long ago?—It ought to have been observed and discovered long ago.

7622. Is there anything else in milk than the albuminoid portion of it which is liable to suffer these changes so as to bring about what are supposed to be the effects of sterilised or pasteurised milk?—The only thing I can think of which would indicate a rearrangement would be the inorganic phosphates.

7623. Supposing there were some slight re-arrangement of the inorganic phosphates?—That would not produce a poisoning effect; certainly not.

Prof. W. L.  
Halliburton,  
M.D., F.R.S.  
etc.

| 1. Law and practice in certain foreign countries as to preservatives and colouring matters in food -                                                                                                                                                                                                                                                                                                                                                                                     | 269   |
| 2. Law and practice in the British Colonies as to preservatives and colouring matters in food -                                                                                                                                                                                                                                                                                                                                                                                          | 275   |
| 3. Report on visit paid to Amsterdam, Hamburg and Denmark, in relation to the use of chemical preservatives in milk and butter -                                                                                                                                                                                                                                                                                                                                                         | 280   |
| 4. Report on a visit to Ireland in relation to the use of certain preservatives in dairying and vegetable products -                                                                                                                                                                                                                                                                                                                                                                     | 292   |
| 5. Report upon visits to two preserved vegetable and fruit factories, together with certain experiments upon the effect of varying the amount of copper used in the preserving process upon the ultimate greenness of the preserved peas -                                                                                                                                                                                                                                               | 304   |
| 6. Report, handed in by Professor Tunncliffe, on experiments upon the effect of boracic acid and formaldehyde upon the live weight, growth, and food assimilation of young sucking pigs -                                                                                                                                                                                                                                                                                                | 306   |
| 7a. Report, handed in by Professor Tunncliffe, upon certain experiments made upon the extent to which the copper ingested with artificially-coppered peas is absorbed and retained by the human body -                                                                                                                                                                                                                                                                                   | 312   |
| 7b. Report, handed in by Professor Tunncliffe, on the influence of formic aldehyde upon the metabolism of children -                                                                                                                                                                                                                                                                                                                                                                     | 313   |
| 7c. Report, handed in by Professor Tunncliffe, on the influence of boric acid and borax upon the general metabolism of children -                                                                                                                                                                                                                                                                                                                                                        | 337   |
| 8. Tables, compiled under the direction of Professor Thorpe, giving the results of analyses of samples of food and drink, made in the Government Laboratory, in relation to contained preservatives and colouring matters -                                                                                                                                                                                                                                                              | 355   |
| 9. Railway transport of milk and butter in England -                                                                                                                                                                                                                                                                                                                                                                                                                                     | 373   |
| 10. An historical record, by Mr. S. A. Vasey, of the use of preservatives and colouring matters in food, gleaned from the volumes of "The Lancet," 1851-99 -                                                                                                                                                                                                                                                                                                                             | 377   |
| 11. Statement, handed in by Mr. T. C. Smith, giving (A) Names of preservatives; and (B) Colouring matters used in various descriptions of dairy produce, and the quantities or proportions in which they are used by persons who have complied with a request for information on these subjects; (C) Names of the preservatives; and (D) Colouring matters mentioned in 110 replies to a circular letter addressed to dairy farmers and traders, with the number of persons using each - | 379   |
| 12. Report, handed in by Mr. Fisher, on behalf of the Society of Public Analysts as to preservatives and colouring matters in food, drinks, and drugs -                                                                                                                                                                                                                                                                                                                                  | 385   |
| 13. Tables, handed in by Dr. A. Hill, as to preservatives and experiments as to preservatives in milk, butter, and other foods in the city of Birmingham, with a statement as to prosecutions in that city in respect of boracised milk and butter, 1896-99. (Tables A to M.) -                                                                                                                                                                                                          | 389   |
| 14. Return, handed in by Dr. W. Williams, of the legal proceedings taken against vendors of milk, butter, and ham containing preservatives, in the county of Glamorgan from March 1897 to November 1899 -                                                                                                                                                                                                                                                                                | 392   |
| 15. Paper, handed in by Dr. H. Handford, relating to (a) Report of Analyses of Milk from Nottingham General Hospital; (b) Recommendations of the medical committee of the Nottingham General Hospital with reference to the supply of milk thereto; (c) Analysis of milk from the same hospital; and (d) Report as to the sanitary condition of certain cowsheds in the Basford Rural District -                                                                                         | 393   |
| 16. Statement, handed in by Mr. W. F. Lowe, as to his personal views on the use of preservatives and colouring matters in foods -                                                                                                                                                                                                                                                                                                                                                        | 393   |
| 17. Letter, addressed to Professor Thorpe by the Government Analyst of British Guiana, relative to the tinting of West Indian sugar -                                                                                                                                                                                                                                                                                                                                                    | 394   |
| 18. List, handed in by Mr. Leonard K. Boseley, of colouring matters used in confectionery -                                                                                                                                                                                                                                                                                                                                                                                              | 395   |
| 19. Letter, handed in by Mr. J. Wheeler Bennett, from the High Commissioner for Canada, giving figures relating to the value of bacon and hams exported from Canada to Great Britain during 1889-98 -                                                                                                                                                                                                                                                                                    | 395   |
| 20. Translation, handed in by Mr. J. W. Copeman, of letter from the Minister of Commerce to the President of the French Chamber of Commerce, with enclosed report of M. Riche, relative to the coppering of peas -                                                                                                                                                                                                                                                                       | 396   |
| 21. Certified copy, handed in by Mr. J. W. Copeman, of an order of the Prefect of La Gironde, relative to the manufacture of greened peas in that department -                                                                                                                                                                                                                                                                                                                           | 398   |
| 22. Statements, handed in by Mr. J. W. Copeman: (a) Table of deaths from food poisoning in England, 1887-95, and (b) As to deaths by poison (accidental), 1888-97 -                                                                                                                                                                                                                                                                                                                      | 398   |
| 23. Tabular statement, handed in by Dr. W. Williams, as to specimens of milk and butter examined in the county of Glamorgan for preservatives, with the results obtained -                                                                                                                                                                                                                                                                                                               | 399   |
| 24. Paper, handed in by Dr. S. Rideal, as to the time milk is kept sweet by the addition of boric acid and formaldehyde at various temperatures -                                                                                                                                                                                                                                                                                                                                        | 400   |
| 25. Extracts, handed in by Major C. E. Cassal, from his annual reports to the vestries of Kensington and St. George, Hanover Square, dealing with preservatives in food, sweetmeats, and wines, during the period 1891-98 -                                                                                                                                                                                                                                                              | 400   |
| 26. Report, handed in by Mr. H. Faber, on experiments made at Copenhagen to test the keeping of fresh butter -                                                                                                                                                                                                                                                                                                                                                                           | 404   |
| 27. Paper, handed in by Mr. H. Faber, containing the opinion of the Minister of Justice at Copenhagen on the effect on health of the use of chemical preservatives in food -                                                                                                                                                                                                                                                                                                             | 405   |
| 28. Tables, handed in by Mr. W. Collingwood Williams, relating to the analyses of milk in the city of Liverpool, and in the administrative county of Lancaster for borates and formalin -                                                                                                                                                                                                                                                                                                | 406   |
| 29. Table, handed in by Mr. W. Collingwood Williams, relative to preservatives in milk during 1899 in the city of Liverpool, the administrative county of Lancaster, and five Lancashire boroughs -                                                                                                                                                                                                                                                                                      | 407   |
| 30. Tables, handed in by Dr. J. R. Kaye, (a) giving a few examples of advertised preservatives; (b) showing the infantile mortality in England and Wales (compiled from the Registrar General's returns), during the twenty years 1878-1897; and (c) Displaying the rates of infantile mortality during one eight-year period (1891-1898) in England and Wales and various parts of the country -                                                                                        | 408   |

|                                                                                                                                                                                                                                                                                                                                                       | PAGE. |

## A P P E N D I X.

### APPENDIX NO. I.

#### LAW AND PRACTICE IN CERTAIN FOREIGN COUNTRIES AS TO PRESERVATIVES AND COLOURING MATTERS IN FOOD. Appendix.

*Summary of data obtained by the Foreign Office.*

##### AUSTRIA-HUNGARY.

No special law obtains. Ministerial decrees are, however, in force prohibiting the use of certain well-known preservatives and colouring matters in foods. Prominent analytical chemists are engaged in preparing a "code" which will, doubtless, form the basis of a law, regulating *inter alia* the use of preservatives and colouring matters. Generally, at present, exceptions to prohibition of preservatives are made only in respect of salt in butter to 5 per cent., and both salt and saltpetre to unlimited extent in meat preservation. Opinion divided as to salicylic acid, as it is used medicinally up to one-gramme doses, and small quantities are tolerated in foods not likely to be given to children or invalids. But in milk, salicylic acid, borax, boracic acid, and soda are forbidden. The use of saccharine is especially forbidden, but (?) for commercial reasons only.

In Austria-Hungary a decree of 1866 forbids in food the use of any colouring matter which contains metals (iron excepted), gamboge, picric acid, or aniline. But in 1895 a large number of aniline dye stuffs which do not contain arsenic were permitted to be used for sweetmeats, liquors, etc., specimens of such colours to be yearly submitted to official examination. Ultramarine only permitted when free from arsenic, and in such small quantity that in a 10 per cent. solution of water its presence is not distinguishable. All harmless vegetable colourings are allowed, and saffron, safflower, chlorophyll, and cochineal are largely employed.

Probable that shortly a decree will permit minute quantities of copper in preserved fruits and vegetables, as infinitesimal amounts, too small to injure health, suffice to preserve colour.

##### BELGIUM.

The Government can by the law of 1890 prohibit the employment of matters dangerous or injurious to health in foods, and a decree of 1896 prohibits the sale of lard or other fats added to antiseptics or glycerine. A decree of 1894 prohibits absolutely the use of preservatives in milk.

##### DENMARK.

Summary of Laws and Regulations in Force.

The law of 1897 prohibits the use of all preservatives, other than cooking salt, in butter or margarine, even for exportation. The Minister of Agriculture may, "under necessary control," allow butter or margarine not in accord with the law, which has been imported, to be either exported or immediately sold for inland consumption.

Articles of food must not be subjected to treatment intended to conceal their deteriorated condition.

The Ministry failed to carry a clause in 1897 which aimed at the prohibition of substances in foods which, while inoffensive in themselves alone, might have dangerous consequences if their absorption was continued.

The sentence referred to runs as follows: "Moreover the Minister of Justice shall be authorised to forbid, by means of regulations to that effect, the addition to food destined for sale, of substances, inoffensive in themselves alone, but whose continued absorption may have dangerous consequences."

As regards this clause the following remarks are made by the Danish Ministry:—

"The manager of the laboratory for chemical analysis employed by the State for the examination of victuals has informed the Ministry of Justice that in this country admixtures to victuals (milk amongst others) are used to rather a high extent with the purpose of preserving these better, that the admixtures most frequently used for preservation are boracic acid or preparations of same and salicylic acid, and that the continual consumption of victuals for the preservation of which boracic acid in larger quantities or salicylic acid has been used, must be supposed to cause danger to the health of the consumers. The Ministry having therefore put the matter before the Royal Sanitary Committee for consideration, they have declared that boracic acid and preparations of boracic acid might have a fatal influence on the state of health, if the quantity of 1 gramme or even less of these substances has during some time been brought into the organism by the consumption of victuals prepared with these substances. Further that boracic acid used as admixture to victuals (milk) for small children might be dangerous even if the quantity is comparatively small, and that the use of salicylic acid and its preparations used for the same purpose should never be allowed on account of the dangerous influence of these substances.

"Several sanitary committees are authorised by local sanitary regulations, for instance by section 31 of the sanitary regulations for Copenhagen, confirmed June 15th, 1886, to take steps against abuses of the above-mentioned kind (eventually by the issue of a general prohibition for the territory of the community concerned). The Ministry is, however, of the opinion that it would be advisable to have similar rules for all communities, and that this could easiest be arranged if the Ministry were empowered to issue a general ordinance to this effect. Considering the circumstances it is undoubtedly an anomaly that the Ministry can issue by ordinance rules as to whether and to what extent substances injurious to the health may be admixed to wine and spirits, while the Ministry has no corresponding power as regards other victuals. This anomaly is the more apparent as the Ministry of Justice in Section 1 of Ordinance of April 17th, 1894 (issued in accordance with Section 5 of the law of April 1st, 1894), has ordained that the above-mentioned substances boracic acid and salicylic acid amongst others should not be allowed to be admixed to produces which are sold as wine or (in accordance with Section 12 of the ordinance), cognac, rum, or ~~etc.~~

## Appendix.

"Provided that the present Bill is passed the Ministry intends to issue an ordinance similar to the one of April 17th, 1894, to be in force from October 1st, 1897, for the following three years.

"Finally it has been thought proper to mention expressly in an inserted clause to Section 6 that whoever infringes the regulations issued in accordance with Section 5 will be subjected to a penalty."

As regards wines and spirits it is prohibited to sell:—

- (a) wines admixed with glycerine,
- (b) a produce as wine,
- (c) produce under the name of cognac, rum, or arrac,

when admixed with any of the following, or other substances which may be injurious to health, namely:—

Alum, or other soluble aluminium salts,  
Barium compositions,  
Strontium compositions,  
Magnesium compositions,  
Boracic acid,  
Salicylic acid,  
Raw spirit (containing free amyl alcohol),  
Raw starch sugar (not chemically pure),  
Kermes,  
Aniline.

It is further prohibited to sell, without a declaration which shall state expressly the nature of the goods, wine to which has been admixed:—

- (1) Saccharine,
- (2) Bouquet substances as ethereal oils, composed ethers, essences, or similar ingredients, or
- (3) Gum or other organic or inorganic substances which might increase the quantity of body of the wine.

It is permitted without declaration:—

- (1) to use the common modern clarifying substances such as albumen, gelatin, isinglass, Spanish earth, etc., or such other similar substances as are not deemed to be injurious to health;
- (2) to correct acidity in wine with pure precipitated carbonic lime;
- (3) to sulphur the casks in the usual manner by burning chemically pure sulphur;
- (4) to pasteurise wine;
- (5) to blend different wines; fully fermented wines must only be blended with wines of the same species.

#### Fully fermented wines.

(usually called "light wines").

The sale of fully fermented wines (red or white) containing more sulphuric acid than 2 grammes neutral sulphuric potash to 1 litre is prohibited.

Declaration is required if other colouring matters than those made of wine are admixed to fully fermented wines (red or white).

The addition of sugar of any kind in substance or in solution to fully fermented wines (red or white) is prohibited unless declared at the time of sale.

### FRANCE.

The Use of Colouring Matters and other Materials containing Poisonous Substances.

A decree dated December 29, 1890, sets out the provisions of the French law as to this matter.

This decree consists of

- 1. A list of colours the use of which is prohibited in the colouration of any foodstuffs whatever.
- 2. A list of certain coal tar derivatives which are exempted from the operation of the general provision above referred to, and which may be used in the colouring of sweetmeats, lozenges, ices, and liqueurs.\*
- 3. A list of colours which are specially prohibited in the colouring of paper or cardboard used for wrapping up any foodstuffs whatsoever.

\* The sanction herein extended to the use of certain colours derived from aniline was apparently the result of the progress made in industrial chemistry in the preparation of the colours in question, such progress being regarded as permitting the use of the specified colours without danger to the public health.

By a recent decree, dated February 16th, 1901, the use of "jaune de naphthol" is sanctioned as a colouring agent for "pâtes alimentaires."

4. The proportions of tin, lead, and arsenic which shall be allowed to enter into the composition of tin-leaves or tin-paper used for wrapping up any foodstuffs whatsoever.

5. The proportions of tin, lead, and arsenic which shall be allowed to enter into the composition of the alloy used for the tinning and retinning of vases and utensils serving for the use of foodstuffs.

6. The proportions of tin, lead, and arsenic which shall enter into the composition of tin vases and utensils destined to contain, or to prepare, any foodstuffs whatsoever.

#### The Use of Preservatives and Colouring Matters in Wine.

By the provisions of the law of January 11th, 1891, Art. 2, the use in wine of products such as sulphuric, nitric, hydrochloric, salicylic, or boric acids is prohibited, while chloride of sodium is only permissible to the extent of 1 gramme per litre. Similarly the use of any colouring matter whatsoever in wine, "vin de sucre,"\* "vin de mare,"\* or raisin wine, is an offence against the law.

#### The Use of Colouring Matter in Margarine.

By the law of April, 1897, colouring matters may under no circumstances be added to margarine.

#### Salicylic Acid.

As a result of representations made to the French Government as to the danger to be anticipated from the use of salicylic acid in the preservation of foods, the question was submitted to the Consulting Committee of Public Hygiene. This body, after analysing many products containing salicylic acid, came to the conclusion that the drug in question was dangerous, not only by reason of the direct effects which it produces upon the organism, but also by its indirect influences in permitting the fraudulent introduction into food stuffs, more particularly into raisin wine and into beer, of other harmful or at least unwholesome substances. The Committee considered that all solid foods and all drinks containing any quantity whatever of salicylic acid or of any of its derivatives were to be regarded as suspicious, and that it was necessary to prohibit the sale of such substances. By an Order dated February 7th, 1881, the employment of salicylic acid as a preservative was prohibited.

#### Formalin.

As regards the use of formalin as a preservative, the Minister of the Interior, in a circular to the Prefects dated October 18th, 1899, states, apparently upon the authority of the Consultative Committee of Public Hygiene, that although the amounts necessary to bring about preservation cannot, strictly speaking, be regarded as toxic, they arrest, or at least retard, the "useful fermentations." This preparation cannot, therefore, be daily used internally, and in a continuous fashion, without serious danger. It is also thought that antiseptics thus used frequently serve not to bring about the preservation of wholesome food, but to hide the alteration of foods of bad quality. In view of these conclusions the Minister of the Interior prohibited the sale of foods containing formalin.

### GERMANY.

By the law of 1879, spoilt goods sold in a state concealing their real condition render the vendor liable to penalty. The same, with penal servitude in addition, holds good of articles sold which are injurious to health.

A Bill is now before the Reichstag dealing with meat inspection, and having concern with the partial regulation of the preservation of meat stuffs.

The German law of 1887 says: "Colours detrimental to health are not allowed to be used in the preparation of food, and of other articles for domestic use intended for sale. Colours injurious to health, within the meaning of this section, are those coloured substances and coloured preparations which contain antimony, arsenic, barytes, lead, cadmium, chromium, copper, mercury, uranium, zinc, tin, gamboge, coralline, picric acid."

The use of vessels, wrappers, or coverings containing colourings of the kind referred to is prohibited in the storing or packing of foods. But "prohibition does not apply to sulphate of barium (sulphate of baryte, blanc fixé), coloured lacs of baryte which do not contain carbonic barium, chromic oxide, copper, tin, zinc,

\* The composition of these wines is defined by the law of July 11th, 1890.

and their alloys, as metallic colours, cinnabar, peroxide of tin, sulphide of tin as mosaic gold, nor of colours baked in glassmetals, glazes, or enamels, nor to the external coating of vessels made of watertight materials."

The law of April 20th, 1892, respecting the treatment of wines and of vinous liquors, viz. :—

"Section 1.—None of the following substances, nor mixtures containing any of them, are to be used in the preparation of wines or vinous liquors destined for human consumption, nor to be added to such liquors subsequently: Soluble aluminous salts (alum, etc.), compounds of barium, boric acid, glycerine, kermes barries, compounds of magnesium, salicylic acid, impure spirits (i.e., containing pure amyl alcohol), impure starch sugar (non-technically pure), compounds of strontium, and colouring tar stuffs."

"Section 3.—The following are not considered as acts of adulteration or counterfeiting of wine in the sense of Section 10 of the Law of May 12th, 1879 :—

"1. The recognised mode of treatment of wines in the cellar, including the methods for preserving them, even though one of the following substances should be added to the wine—alcohol or small quantities of fining substances with mechanically operative qualities (white of egg, gelatine, isinglass, etc.), or small quantities of cooking salt, tannin, carbonic acid, sulphurous acid, or sulphate. In the case, however, of wines which are brought into the market as German wines, the amount of added alcohol should not exceed the proportion of 1 to 100."

The subject of colouring matters in sausages and chopped meats has also engaged the attention of the Imperial Board of Health.

#### ITALY.

Colouring of margarine is prohibited for fraud purposes. By the law of 1894, prohibited noxious colours in preparation of foods are to be scheduled, and this also as regards wrappers for foods.

#### NETHERLANDS.

In the Netherlands, by the law of 1889, butter must not contain any foreign ingredients except salt and colouring matter.

The following is a translation of a Note from the Government on the general question of the use of preservatives and colouring matters :—

The inspector of the State Medical Service in Zealand and Westerly North Brabant mentions the following as preservatives used in his district :—

1. Salicylic acid in beer and currant juice.
2. Saltpetre alone or mixed with borax in meat.
3. Borax and boric acid in milk and butter.

And as colouring matters :—

1. Aniline in artificial lemonades, sugar work, and confectionery.
2. Carmine in sausages.

As regards the injurious character of the aforesaid preservatives there is little to be said, as it depends in a great measure on the quantities that are used.

The colouring matters above mentioned may be classed among the harmless materials provided that the aniline, as seems to have been the case of late years, is free from arsenic.

According to the Inspector for Gelderland and Utrecht, caramel (in vinegar), salicylic acid, borax are used as colouring and preservatives, and are harmless, and Schweinfurt green, chromat yellow, lead mixtures, etc., are used, and must be accounted dangerous.

The Inspector for North Holland has made the accompanying return of colouring and preservatives, found by the Communal Sanitary Service of Amsterdam, in various food stuffs. A note is made that among them are :—

1. Some that may have an injurious effect on the health.
2. Some that, although if they are taken only once, are not to be considered as directly injurious, still if persistently taken may be considered as injurious to health.
3. Some that, although themselves harmless, when mixed with injurious substances, e.g., aniline colouring matters with arsenic, may have an injurious effect, either directly, or after having been taken for a long time.
4. Some that, although perfectly harmless in themselves, e.g., annatto, are used to make up food stuffs of bad quality, e.g., diluted milk to appear of good quality.

The Inspector for Friesland and Groningen makes mention of the occurrence of salicylic acid in beer. In most cases the quantity of salicylic acid added for preservation weighed less than 10 grammes per hectolitre. Salicylic acid is also used for preserving the juices of fruit. The use of colouring materials has been now and then detected.

He goes on to say that so far as he knows no injurious results have ensued from the use of food stuffs or drinks mixed with salicylic acid in the usual quantity, but that in no case the addition must be considered as free from injurious effects, as that depends upon the quantity and the frequent consumption.

The Inspector for Overijssel and Drenthe makes mention of a report received from the examiner of food stuffs at Zwolle, from a chemist, relating to three preservatives for meat, which he had submitted for examination. The first, an English article, with the name of "Meat Preserve Crystal," consisted of sulphuric acid soda, the second named "preserving salt," a mixture of boric acid, saltpetre acid, and kitchen salt, the third named a "Harmless preservative" of sulphuric acid, lime, and water, containing sulphuric acid.

These articles seem to be much in use. We need not fear that they will do much harm, and only the last one would perhaps produce symptoms of poisoning. But the chief danger lies in the circumstance that the recognisable marks of decomposition are disguised by the sulphuric acid, so that the control on tainted meat is impossible. There is no law in this country relating to the examination of foodstuffs as to the presence of injurious preservatives or colouring matters. This subject is regulated by the instructions of the communal authorities.

Adulteration of foodstuffs is made punishable in Art. 330 of the Criminal Code, which runs as follows :—"All persons selling, offering for sale, or delivering foodstuffs or drinks or drugs, knowing them to be adulterated, and not mentioning that adulteration shall be punished with imprisonment not exceeding three years.

"Foodstuffs or drinks or drugs are considered as adulterated whenever their value or their usefulness is diminished by their mixture with foreign substances."

Return of Colouring Matters and Preservatives found in various Food Stuffs and Articles of Consumption by the Communal Sanitary Service.

| Food-stuff or Article of Consumption. | Colouring Matter.                                                     | Preservative.                                                                                    |
|---------------------------------------|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Milk . . .                            | Orlean or annatto . . .                                               | Formaldehyde, borax, boric acid, preserving salt (= boric acid + sodium nitrate + kitchen salt). |
| Butter . . .                          | Aniline (=                                                            | —                                                                                                |
| Cheese . . .                          | Victoria yellow . . .                                                 | Linoscorium or cheese preservatives.                                                             |
|                                       | Orlean . . .                                                          | = water glass + a little ferrocyan mixture + spore of chloride and sulphuric acid mixture.       |
| Wine . . .                            | Fuchsin . . .                                                         | Salicylic acid.                                                                                  |
| Cognac . . .                          | Caramel.                                                              | —                                                                                                |
| Beer . . .                            | . . .                                                                 | Salicylic acid.                                                                                  |
| Currant juice . . .                   | . . .                                                                 | Salicylic acid and sulphuric acid.                                                               |
| Liqueurs . . .                        | Aniline colouring matters.                                            | —                                                                                                |
| Lemonade . . .                        | . . .                                                                 | Salicylic acid. Benzoic acid.                                                                    |
| Sugar-work . . .                      | Aniline colouring matters, ultramarine, death's head, oxide of zinc.* | —                                                                                                |
| Saffron . . .                         | Aniline colouring matter, red chalk.                                  | —                                                                                                |
| Fruit-jelly . . .                     | . . .                                                                 | Salicylic acid.                                                                                  |
| Gherkins . . .                        | Sulphate of copper . . .                                              | —                                                                                                |
| Sausages . . .                        | Fuchsin, cochineal . . .                                              | Bisulphate of calcium.                                                                           |
| Meat . . .                            | . . .                                                                 | Bisulphate of calcium or sulphate of calcium.                                                    |

\* A green colouring matter = Berlin blue + oxide of zinc + sulphate of antimony.

## Appendix.

## NORWAY.

STATEMENT as to the use of preservative and colouring matters for the preservation and colouring of foodstuffs in Norway and their effect upon health, compiled by Mr. T. F. Somerville, of Christiania.

Authorities consulted:—

Reports by Mr. L. Schmelck, Public Analyst to the City of Christiania.

Reports from the Christiania Board of Health.

The Criminal Code of Norway.

"*Forfalskning af Levnetsniedler*," by Mr. E. Simonson, Analytical Chemist and Government Stipendiary.

Discussion before the Criminal Law Commissioners respecting the question of imposing penalties for the falsification of articles of diet.

Newspaper reports: Various.

The use of Preservative and Colouring matters for the preservation and colouring of foodstuffs in Norway, and their effect upon health.

The question of the admissibility of preservative and colouring matters in connection with articles of diet, and the effect upon health of several such substances, has been the subject of much discussion in Norway of late years, as the law existing hitherto is unable to cope with the difficulties that arise—in fact, the only paragraph in the Criminal Law directly dealing with the adulteration of food in general, seems only to provide punishment for persons who either wilfully put poisonous substances into food, or who, after accidentally or in ignorance having mixed such things as could endanger the life or health of their fellow creatures with food, neglect doing all in their power to avert the possible consequences when made aware of the danger. No punishment under the criminal law is attached to adulterations of uninjurious nature. There are, of course, some special laws, such as those regulating the excise, prohibiting certain substitutes or surrogates, as saccharine for malt in brewing, or of margarine for butter; but the law has been found so deficient and unsatisfactory on the whole, that a new special law has been drafted and will be introduced shortly in the Legislative Assembly (*Storting*).

In the course of the discussions which have taken place preparatory to drafting the new law, the most valuable evidence is probably that of Mr. L. Schmelck, the Public Analyst to the City of Christiania.

Mr. Schmelck mentions as the principal preservative at present used for meat, sulphite of soda. This powerful preservative first came into use in Christiania about 14 years ago, and as then applied to the outside of carcasses or even to joints of meat, was not considered injurious to health. Sulphite of soda not only keeps meat perfectly fresh for a considerable time, but it improves the appearance and enhances the bright colour of the meat. Moreover, it is able to restore, to a very great extent, the appearance, smell, and taste even of meat that has already become bad.

Owing probably to the toughness of most kinds of meat in Norway, a very large proportion of the butchers' meat consumed in Christiania, and in the towns generally, is sold in a minced condition, either plainly minced, to be made up into "Vienna beef-steaks," "meat cakes," or "minced collops," or as sausage-meat or forced-meat.

The minced-meat sold in Christiania has been more and more treated with sulphite of soda, until it has become the rule, instead of the exception, to find it mixed with from 0·2—two-tenths of one—per cent., to 1·0—one—per cent., while the brightening and preservative effects upon fresh meat are observable when only 0·05—half of one per thousand—is used.

There could be no doubt that the actual consumption of such comparatively large quantities of sulphite of soda might be dangerous to health, and there would be great difficulty in effectively controlling a limited percentage of this preservative if sanctioned—and danger might arise through meat, that was unfit for food, being restored to an apparently eatable condition. The Christiania Board of Health, therefore, recently stepped in and prohibited the sale or exposure for sale of viands containing any sulphite of soda. The butchers and meat-salesmen, sausage-makers, and others continued, nevertheless, to use the preservative, and a test case has just resulted in a conviction.

The new law, above alluded to, will doubtless provide stringent measures to prevent adulteration.

Boracic acid is occasionally found, in both butter and margarine, and a preserving medium obtained from England, which has been used by some manufacturers of margarine, has been found to consist of about 60 per cent. boracic acid, 30 per cent. saltpetre, and 10 per cent. chloride of soda (common salt). The Board of Health has taken measures to prohibit the use of boracic acid for the preservation of food-stuffs.

The colouring matters generally used have not been considered injurious (*annatto* and the German "*butter-gelb*"), but aniline has occasionally been detected.

Benzoic acid has been found to the extent of 0·1, one-tenth of one per cent., in sacramental wine that was free from alcohol, and this has been prohibited.

Aniline colours are frequently used in fruit-syrups and effervescing beverages, but the Board of Health has not found it necessary to do more than caution certain manufacturers and to let the public know, through the Press, what to avoid, and the use of such matters is diminishing.

Crocein, eosin, and other artificial colourings are used by sausage manufacturers, and are found in many imported sausages.

Of injurious additions detected in imported food-stuffs, the principal are boracic acid in English and American horse-flesh, and oxide of zinc in American dried apples, copper in French "*Petits pois*" (tinned green peas), but only occasionally in such quantities as to be dangerous to health. The amount of oxide of zinc in American dried apples has, however, been at times so great as to lead to their confiscation (0·004 to 0·256 per cent.)—the zinc is not purposely added, but its presence is due to the apples being dried on zinc, or so-called "*galvanised*" sheets.

Wines.—Owing to various Treaties of Commerce, the Customs duty on wines is very small, being only 11·5 Ore (eleven ore and a half, or less than three half-pence) per litre on wines containing up to 23 per cent. in volume of absolute alcohol; and as the Customs duty on imported spirits is very heavy, and even the excise duty on the native brandy exceedingly high, the cheapest intoxicant obtainable is wine fortified up to the limit. Moreover, wine is sold by all sorts of tradesmen; for instance, by nearly all tobacconists, pastry-cooks, bakers, etc., as well as by all grocers, and at all kinds of restaurants and inns, while spirits are only sold in some of the large towns. The natural consequence is, that adulterated "wines" of the "*Ham-burg*" type, which retail at sixpence a bottle, have been imported of late years in enormous quantities, and the Government has taken special measures to endeavour to rectify the evil, and rigorously requires proof to be furnished that the wine has been sent direct from the country of origin without any subsequent doctoring.

Spirits.—The "*Aquavit*" or ordinary native brandy is now-a-days more often distilled from potatoes than from corn. It is usually a pure, silent spirit, flavoured with carraways, and the strength is from 32 to 45 per cent. of pure alcohol by volume, which may probably correspond with the usual "bottling strength" of most whiskies, viz., from 15 or 20 degrees below proof, up to about proof. Some samples have contained somewhat large quantities of amyl alcohol, and traces of formaldehyde, etc., but there does not appear to be any complaint of adulteration in the ordinary "*aquavit*." The same spirit is, however, also made up into imitation cognac, and other liquors, which must contain considerable quantities of flavouring and colouring matters.

So soon as the new law is passed and comes into force, it will be possible to deal with a number of adulterations, which at present cannot be attacked by the Board of Health, or by any special Act, but which render the goods purchased other than what they ought to be—either by concealing defects or enhancing appearance, or by being partially or wholly substitutions or adulterations of inferior or worthless, though innocuous matter.

## SWEDEN.

TRANSLATION of a document containing details of the legislation on the subjects of preservatives and colouring matters in food.

In the documents annexed to the dispatch\* there are three questions to which answers are especially desired.

\* Not here reproduced.

These are .—

(1.) Whether the use of such means, or any of them, for preserving or colouring articles of food in certain quantities is dangerous to health, and in that case, in what proportions the using of them becomes injurious.

(2.) To what extent and in what quantity are they used at present?

(3.) What may be considered to be the quantity of the additions, their nature, and relative existence?

Regarding questions 2 and 3, the following may be said :—

Already six or seven years ago a preservative for meats was introduced into the trade in Stockholm, named "Best Australian Meat Preserve."

On being chemically examined here, this preparation was found to consist of a solution of sulphurous acid lime. It was stated to be composed of 22.5 grammes lime and 77 grammes sulphurous acid to one litre of water.

This preservative, which was pretty generally used by meat dealers, butchers, and sausage makers here, especially during the warm season, has, however, now, and particularly during the last two years, been more and more driven out by preservatives in dry form, viz., partly a preparation called preservalin, partly another preservative salt, which, to some extent, is imported from Germany, and is also manufactured at a couple of places in this country.

In pursuance of the dispatch from the Royal Medical Board of Health ("Konglig Medicinalstyrelsen") I have taken samples of colouring and preservative matters at all the sausage-making establishments in the capital, and they have in the majority of cases been found to consist of either of the preparations mentioned below :—

The "Preservalin"—preserving salts that are used here are, according to statement, manufactured by the Preservalin Manufacturing Company, New York, and other places in America.

They are named A, B, and C Preservalin.

Preservalin "A" is a white powder, which, according to the chemical analysis made at my request by Mr. K. Sondén, Engineer and Chemist to the Board of Health of Stockholm, consists of common kitchen salt and borax.

Preservalin "A" is intended to be used for the preserving of fresh meat, pork, meat—and liver—sausages, etc., and it is stated in the directions for use that the quantity which is required in order to obtain a good result ought to be one kilogramme to 500 kilogrammes of meat.

Preservalin "B," which is used both for preserving and colouring all kinds of smoked sausages, is composed of a pale red (pink) salt, which, according to an analysis made by the said Mr. Sondén, was found to consist of common kitchen salt and saltpetre, together with some organic colouring matter, and should, according to the directions for use, be employed in a dose of 100 grammes to 20 kilogrammes of meat.

As regards the rest of the preservative salts which are used here, the domestic ones are generally called only preserve-salt ("Konservsalt"). Some of these articles are imported from Germany, from the firms of O. Leidler, Wernigerode a/H., Leonard and Marins, of Berlin, and others, under the name of "Meat Preserve Crystal."

These last-named salts have, according to an analysis made by Mr. Sondén, been found to be composed of sodium, sulphite, and sulphate.

Very recently and last of all, two new preservative substances have found their way into the trade, "Zanzibar Carbon" and "Freeze-em." These preparations, the former of which also serves as colouring matter, are manufactured by Messrs. B. Heller and Co., Chemists, Chicago, United States, America, and consist, according to an analysis made at the Reichsgesundheitsamt, Berlin, the former of 75 per cent. of common kitchen salt and 25 per cent. Bismarck brown, the latter of water free sodium-sulphite with 15.6 per cent. of sodium-sulphite and traces of chloride of sodium and sodium carbonate.

"Zanzibar-Carbon" is chiefly used for so-called after colouring of smoked sausages, which process is done by the sausages being boiled in water to which

"Zanzibar-Carbon," in a dose of one teaspoonful to 300 litres of water, has been added. Appendix.

I have received information from Mr. C. L. Blomgren, Town Veterinary, Gothenburg, regarding the use of colour and preservatives for the colouring and preserving of meat and food prepared therefrom, to the effect that "meat-preserve" and "meat preserve-crystal" are chiefly used there, which preparations likewise contain sulphurous acid natron.

In Gothenburg, candies and mannacroup have been found in the trade coloured with chromate of lead, and in jams and fruit-juices salicylic acid has been found.

In a sample of varnish used for smearing hams in order to give them a nice colour and a shiny surface, arsenic has been found by the Town Chemist, Gothenburg.

Hydrate, according to the opinion of the Town Veterinary, Gothenburg, is sometimes used for the preserving of herring and anchovies.

The Town Veterinary furthermore refers to the report of the Gothenburg Board of Health for the years 1897 and 1898 :—

In the former it is stated, among other things on this subject, on page 39, as follows :—

Some hydrate preparations accessible to the public have been examined for the Board of Health.

(1) Preservitas from the Preservitas Co., London.

(2) Ordinary antiseptic fluid ("Enkel Aseptin").

(3) Double antiseptic fluid ("Dubbel Aseptin").

Both these last are from Henrik Gahn's Aseptin, Amykos Co., Limited, Upsala, Sweden.

The analyses of these preparations have given the following results :—

|                                    | Preservitas. | Ordinary Antiseptin "Enkel Aseptin." | Double Antiseptin "Dubbel Aseptin." |
|------------------------------------|--------------|--------------------------------------|-------------------------------------|
|                                    | Per Cent.    | Per Cent.                            | Per Cent.                           |
| Hydrate . . . . .                  | 78.92        | 99.95                                | 77.19                               |
| Common kitchen salt . . . . .      | 9.20         | —                                    | 22.81                               |
| Saltpetre (Kaliumnitrat) . . . . . | 9.53         | —                                    | —                                   |
| Other (humid matters) . . . . .    | 2.34         | 0.05                                 | —                                   |

Regarding the sale prices of these preparations it may be mentioned that :—

1 kilogramme of Preservitas costs 2.62 öre (2s. 11½d.),

1 kilogramme of Ordinary Antiseptin costs 2.94 öre (3s. 3d.),

1 kilogramme of Double Antiseptin costs 3.00 öre (3s. 4d.),

while the chemist's shop "Enhörningens" Drug Stores, here, according to its price-list, charges 70 öre (9½d.), for acidum boricum venale, "borsyra."

In the spring a quantity of herring was found in a fish dealer's store preserved in hydrate. Of this herring, as well as of the brine in which it was packed, a health officer took a sample which was examined as to its hydrate percentage, with the following result :—

Herring. Herring brine.

Hydrate ("Borsyra") 0.83 per cent. 1.59 per cent.

In the Report for the year 1898, it says on page 42 :—

A meat preservative named "Meat Preserve" from the factory Saturnus, at Malmö, Sweden, F. G. Borg, Apothecary, owner, has been examined on behalf of the Board of Health. It showed a pale, yellowish, somewhat turbid fluid, with a strong odour of sulphurous acid, being of an actual weight, at 15 degrees Centigrade, of 1.074.

There was in a litre of this fluid :—

Solid matters (after evaporation and drying) . . . . . 50.4 grammes

Sulphurous acid . . . . . 83.4 ..

The sample chiefly consisted of a water-solution of acid sulphurous lime.

## Appendix.

After this résumé of the different preservatives and colouring matters which at present are used in the two largest towns in Sweden, question (1) remains to be answered, viz. :—"Whether the use of such matters for preserving or colouring foods in certain quantities is dangerous to health, and in that case, in what proportions the using of them is injurious."

The injurious effects of the preservatives in question, irrespective of their different characters, depends of course to a great extent on how they are used.

The manner of using them is very different in different places.

While some tradesmen apply the preparations in accordance with prescriptions, others handle them entirely at random, indeed, so carelessly that they can hardly tell the approximate quantity that is used by them for the colouring and preserving of the various foods.

With respect to the question of the injurious effects of the preservatives, it may be said that sulphurous acid certainly is a good preservative for the muscle colouring matter ("muskelfärgämnet"), but not for the meat itself. By employing sulphurous acid-salts the meat can be made to retain its natural colour, even after it has become tainted, and in this there is no small danger, inasmuch as the buyer by this means easily can be misled regarding the actual quality of the meat, and especially of mince meat—since old mince meat and sausages can be sold as fresh, for the changes of colour which otherwise take place in the muscle colouring matter ("muskelfärgämnet"), after the adding of the salts, do not appear at the same time as the tainting sets in.

An addition of sulphurous acid-salts makes it furthermore possible to add water to mince meat without it losing the colour of fresh meat.

Shorer has furthermore pointed out that the mixing of sulphurous acid and its salts may be disadvantageous even to the seller, because the sulphurous acid often is turned into hydrogen sulphide, which, owing to its disagreeable smell, makes the meat entirely unsaleable.

This observation is fully in accordance with the opinions of the better class (that is to say), the most honest, sausage makers in Stockholm, who consider that the use of such artificial preservatives and colouring matters can damage the reputation of the profession, and therefore they have declared that they would have no objection to their prohibition. These men say they have been compelled to adopt them in order to enable them to compete with the tradesmen who began using them.

As regards the suitability of sulphurous salts added to mince meat, etc., and its sanitary significance, the Imperial Board of Health at Berlin (Das Kaiserliches Gesundheitsamt) has expressed itself as follows :—

1. From fresh butcher meat without chemical preservatives, but with due observance of cleanliness, mince meat can be produced, which, if kept at a low temperature, will retain its natural colour for more than 12 hours.

2. The addition of preservatives which contain sulphurous acids and similar salts can improve the natural colour of the meat, but not the meat itself. By their means mince meat can appear to be of better quality than it really is.

3. The frequent consumption of mince meat which is treated with sulphurous acid salts may be injurious, particularly to people of delicate health.

The whole profession will certainly agree with this expression of opinion, given by such expert authorities as the Imperial Board of Health of Berlin, and to my knowledge this opinion is the prevailing one among the controllers of meat in Germany.

## SWITZERLAND.

No Federal law, but several cantonal enactments prohibitive of preservatives.

In the Canton of Zurich a law of 1896 prohibits the employment of all preservatives save cooking salt and saltpetre, but borax continues to be largely used.

The following is a translation of extracts from a letter from the Government, dated September 5th, 1899 :—

... We forward a reply to your request, only regretting that the circumstances, which we shall explain to you, do not permit us to give you information as precise as we should have desired.

In the absence of a federal law upon the regulation of foods there are the cantonal laws and ordinances which regulate for the moment the employment of antiseptics and colouring matters in the preparation of these commodities.

It will be difficult, if not impossible, to inform you upon the importance which the employment of antiseptics and colouring matters in the manufacture of foods has received in our country; there exists, in fact, neither publications nor documents which give us upon this subject precise information. We only possess the reports of the cantonal chemists—that is to say, the chemists who in certain cantons are charged with the control of foods. But it is easy to understand that with the multiplicity and the diversity of our cantonal legislations, these reports, which besides are only published by a small number of cantons, can only form a base for estimation upon the question which occupies us. Therefore we will confine ourselves to extracting the most important from among them. These may perhaps afford some information which will be useful.

Laboratory of Canton of Bâle-Viele, 1897.—18 per cent. of the sausages examined (20 out of 111) were artificially coloured, for the most part by an aniline dye, orange R. Two samples of raspberry lemonade were in reality coloured by means of an aniline dye. A product imported from England under the name of Queen's Lemon Squash consisted of a dilution of citron juice added to about 5 per cent. of salicylic acid.

The same laboratory, 1898.—Two samples of margarine contained boric acid.

A salt preserve manufactured at Wittenberg and sold under the name of "Meat Preserve Krystal," was a compound of sulphite of soda and Glauber's salt. A bit of meat treated by means of this salt contained 172 milligrammes of sulphurous acid per 100 grammes. Fifteen samples of sausages were artificially coloured. A lemonade was coloured by means of an aniline colour, the odour of which resembled that of naphthylamine. This colour was seized and destroyed upon the premises. All manufacturers of lemonade with the exception of one, who only uses a syrup of raspberries, use for making their products aniline essences and colours without giving a special designation to their lemonade.

Laboratory of the Canton of Zurich.—Although an order of 19th December, 1896, prohibits the employment for the preservation of meats of other substances than cooking salt and saltpetre, in 1897 out of 55 specimens of meat examined at the laboratory 27 still contained boric acid or borax, the same substances have been found in six samples of sausages, five other samples of sausages were coloured by means of an aniline dye. Out of 2,032 samples of wine examined one alone was artificially coloured.

Laboratory of the Canton of St. Gall.—At St. Gall foods coloured artificially or preserved by the aid of antiseptics appeared especially to come from abroad. Thus samples of American meat examined in 1897 and 1898 contained boric acid. Dried apples of American production contained traces of zinc (1897 and 1898). In 1898 the laboratory has had to analyse Austrian butters coloured artificially or treated with salicylic acid.

Laboratory of the Canton of Thurgovie.—The greater part of the American meats analysed in 1897 contained boric acid.

Laboratory of Canton of Berne.—Colouration of pastry by "jaune de Martius" tends to disappear; in 1897 only two samples were found coloured by this process; in practice inoffensive colours are employed. A preserve of yolk of egg examined in 1896, and coming from Germany, contained salicylic acid. The laboratory has often enough had to analyse wines sulphured or clarified too much with gypsum. Some samples contained as much as 186 milligrammes of free sulphurous acid per litre; others as much as 47 grammes of sulphate of potash per litre (limit allowed two grammes). However, wines too much clarified with gypsum are becoming rare. Such are some extracts which we have been able to take from the reports of the cantonal chemists during recent years. They do not permit of a complete account being stated of the amount in which the processes of manufacture, which the English Committee proposes to study, are used in Switzerland. One is able only to conclude from it that these processes are utilised by our manufacturers. We greatly regret not being able to furnish you with indications more complete and more precise.

We are, etc.,

(Signed) HAUSER, Vice-President.

## UNITED STATES.

No maximum limit laid down as to preservatives. But those having no marked toxic character not absolutely prohibited. All packages to bear testimony to amount and name if any used.

As to colouring matters no maximum limit fixed. But it is well known that aniline dyes have a retarding effect on digestion. No colouring matter to be used unless each package bears testimony to name and amount. No absolute prohibition of any colouring matter which has no marked toxic character.

Extract from the report of the Secretary of Agriculture, U.S.A., to the President for the year ended June 30th, 1899.

Careful and systematic research has been made in the division of chemistry for preservatives of all kinds which may have been used on meats. The attitude which the department should take toward preservatives has been frequently outlined in official reports, but it may be as well to restate it here, as the matter is of great importance.

It is not regarded as a wise thing to absolutely prohibit the use of preservatives in foods. Since, however, all chemicals which have the properties of preserving foods have also a tendency to interfere with the processes of digestion, it is held to be imperative that no food should be offered for sale which contains a preservative without having this fact plainly stated upon the label of the package. Not only should the label state that the food product contains a preservative, but it should also give the name of the preservative and the quantity employed. In this way the intending purchaser is fully informed in regard to the character of the product which he buys. While it has been established that a healthy stomach can, from time to time, receive with impunity food containing small quantities of preservatives, it is by no means certain that the continued practice of ingesting preservatives in foods would not produce serious injury. On the other hand, it is also quite certain that weak or diseased stomachs may suffer temporary or permanent injury from minute quantities of preservatives.

The following are among the enactments in force in the State of Illinois bearing on the subject:—

Be it enacted by the people of the State of Illinois, represented in the General Assembly, that no person shall mix, colour, stain, or powder, or order or permit any other person in his or her employ to mix, colour, stain, or powder any article of food with any ingredient of material, so as to render the article injurious to health, or depreciate the value thereof, with intent that the same may be sold; and no person shall sell or offer for sale any such article so mixed, coloured, stained, or powdered.

No person shall coat, powder, or colour with annatto or any colouring matter whatever, any substance designed as a substitute for butter, whereby such substitute or product so coloured or compounded shall be made to resemble butter, the product of the dairy.

Vinegar shall not Contain Lead, Copper, or Sulphuric Acid.—No person shall manufacture for sale, offer for sale, or have in his possession with intent to sell, any vinegar found upon test to contain any preparation of lead, copper, sulphuric acid, or other mineral acid, or other ingredients injurious to health. All packages containing vinegar shall be marked, stencilled, or branded on the head of the cask, barrel, or keg containing such vinegar, with the name and residence of the manufacturer or dealer, together with the brand required in Section 16 of this Act.

Canned Goods to be Free From Articles Deleterious to Health.—No packer or dealer in preserved or canned fruits and vegetables, or other articles of food, shall sell or offer for sale such canned or preserved fruits and vegetables or other articles of food, unless they shall be entirely free from substances or ingredients deleterious to health, and unless such articles bear a mark, stamp, brand, or label, bearing the name and address of the firm, person, or corporation that packs same or dealer that sells same. All soaked or bleached goods or goods put up from products dried before canning, shall be plainly marked, branded, stamped or labelled as such, with the words "soaked" or "bleached goods" in letters not less than two-line pica in size, showing the name of the article and name and address of the packer or dealer who sells same.

Fruits, Jellies, and Jam.—No person shall manufacture for sale, have in his possession with intent to sell, offer or expose for sale, or sell, as fruit, jelly, jam, or fruit butter, any jelly, jam, or imitation fruit butter, or other similar compound made or composed, in whole or in part, of glucose, dextrine, starch, or other substances, and coloured in imitation of fruit, jelly, jam or fruit butter; nor shall any such jelly, jam, or fruit butter or compound be manufactured or sold, or offered for sale, under any name, or designation whatever unless the same shall be composed entirely of ingredients not injurious to health; and every can, pail, or package of such jelly, jam, or butter sold in this State shall be distinctly and durably labelled "imitation fruit, jelly, jam, or butter," with the name and address of manufacturer or dealer who sells same.

All baking powders sold in the State must be labelled in a conspicuous way and place with a name signifying the class or variety to which it belongs, based on the name of the acid ingredient; thus, for example, "This is an alum baking powder; an alum phosphate baking powder; a phosphate baking powder; a cream of tartar baking powder." Potassium acid sulphite is regarded as unwholesome, if not injurious, and its use in any article of food is prohibited.

## APPENDIX No. II.

## LAW AND PRACTICE IN THE BRITISH COLONIES AS TO PRESERVATIVES AND COLOURING MATTERS IN FOOD.

(Summary of data obtained by the Colonial Office.)

## AUSTRALIA:—

## (1) SOUTH AUSTRALIA.

Preservatives such as boracic acid, formalin, and salicylic acid are met with in dairy produce, and also colouring matters. Boracic acid is the predominating chemical substance used in this colony as a preservative, and it is invariably added as a component in a compound known as "Preservitas." The percentage of boracic acid contained in "Preservitas" is believed to exceed 70. Formalin and salicylic acid when put into milk and butter are regarded as of considerable danger to consumers. Colouring matters are used by all butter and cheese manufacturers, but when the preparations are of purely vegetable origin, little danger is apprehended from their presence.

The Dairy Instructor says that butter containing 1 per cent. of boracic acid is probably unsafe to the consumer. In this colony 8ozs. to the 100lbs. of butter is regarded as a safe and sufficient quantity.

Colouring matters are sold of varied strengths, so that a fixed proportion cannot be recommended. Law of 1882 is on the lines of the Tasmanian law of 1885 (*see later*), but there is a clause in the law of 1890 which declares that in the case of food which is a mixture, or which has an admixture of an ingredient or ingredients not generally known and recognised as a natural and necessary component part of that food, and is mixed therewith by way of adulterating it, or is an artificial imitation of an article of food, a label shall

Appendix. *be affixed* to that food, specifying the names of each of the matters or ingredients with which such food is mixed or adulterated.

## (2) QUEENSLAND.

Law of 1881 as in Tasmanian Act of 1885 (*see later*).

As to the legal aspect of the matter, the Attorney-General is not aware of any law in force in Queensland which expressly authorises the use of any matter in connection with food for the purpose of preserving and colouring the same, but that there are several Acts in force which provide for the punishment of persons who mix any colouring or other matter with any articles of food, which are deleterious or such as to render the article injurious to health.

The Under Secretary says that so far as agriculture is concerned the use of preservatives in Queensland is confined principally to butter and cheese. With regard to the former the use of certain preservatives is prevalent to some extent in dairies and creameries. The factories, too, in some instances, use preservatives again in the cream arriving at the creameries by rail, especially during the hot weather. These are commercially known as *Preservitas*, *Sal Preservare*, and *Preservaline*. There are others in use in a minor degree, but these are the principal and analyses of them as taken by the Agricultural Chemist show:—

### *Preservitas.*

|                |                                   |                 |
|----------------|-----------------------------------|-----------------|
| Water - -      | H <sub>2</sub> O - -              | 34.50 per cent. |
| Soda - - -     | Na <sub>2</sub> O - -             | 5.58 "          |
| Boric Acid - - | B <sub>2</sub> O <sub>3</sub> - - | 47.39 "         |
| Salt - - -     | NaCl - -                          | 9.33 "          |
| Saltpetre - -  | KNO <sub>3</sub> - -              | 3.00 "          |
|                |                                   | <hr/> 99.80 "   |

A mixture of 34 per cent. borax, 9 per cent. common salt, 3 per cent. saltpetre, the rest being boric acid.

### *Sal Preservare.*

|                |                                   |                 |
|----------------|-----------------------------------|-----------------|
| Water - - -    | H <sub>2</sub> O - -              | 34.30 per cent. |
| Soda - - -     | Na <sub>2</sub> O - -             | 4.96 "          |
| Boric Acid - - | B <sub>2</sub> O <sub>3</sub> - - | 51.80 "         |
| Salt - - -     | NaCl - -                          | 8.52 "          |
|                |                                   | <hr/> 99.58 "   |

A mixture of 30 per cent. borax, 8.5 salt, the rest being boric acid.

### *Preservaline.*

|                |                                   |                 |
|----------------|-----------------------------------|-----------------|
| Water - - -    | H <sub>2</sub> O - -              | 37.70 per cent. |
| Boric Acid - - | B <sub>2</sub> O <sub>3</sub> - - | 40.60 "         |
| Salt - - -     | NaCl - -                          | 20.16 "         |
| Saltpetre - -  | KNO <sub>3</sub> - -              | 3.03 "          |
|                |                                   | <hr/> 101.49 "  |

A mixture of 20 per cent. common salt with 3 per cent. saltpetre and boric acid.

It is difficult to give an authoritative opinion upon the injurious effect of these preservatives, for no thorough investigation has been made in this direction. The danger would perhaps seem to lie rather in the misuse than the use, and it is the cheap chemicals that have to be feared most. The fact, however, remains that authorities upon dairies in Queensland (excluding manufacturers) are adverse to the use of preservatives.

To what extent and in what amounts they are used at the present time cannot be answered definitely, since no direct investigation has been made.

The Government analyst says that the law on the subject is included in sections 2 to 8 under heading "Description of offences" in the "Sale of Food and Drugs Act of 1881," these sections being identical with Sections 3 to 9 in the English "Sale of Food and Drugs Act of 1875," so that Queensland is in practically the same position as England in this matter. So far as he is aware no prosecutions have taken place in Queensland for the use of preservatives in food, although, owing to the hot climate, preservatives are almost universally used.

The fact that some qualified medical practitioner can almost invariably be brought into court ready to swear

to the harmlessness of preservatives, and that the general practice in such cases is to give the accused "the benefit of the doubt" owing to conflicting medical evidence, instead of giving the public the "benefit of the doubt," has prevented certificates from being issued as to preservatives being deleterious; and the lack of evidence has prevented the fixing of any standard as to the amounts of the various preservatives which should be considered injurious to health.

With regard to colouring matters the only prosecutions so far as known in Queensland were for the use of Roseaniline in wine, and a conviction was obtained in each case.

The public analyst of South Brisbane says that borax, boric acid, formalin, salicylic, and benzoic acids, are frequently found to have been added to articles of food as preservatives. In the summer months milk, butter, and cream, are kept for a considerable time by the addition of borax, boric acid, or mixtures of these two substances under various fanciful names, and formalin, although only recently introduced, is likely to be widely used for this purpose, as an addition of so small a quantity as 0.05 per cent. is sufficient to keep milk for weeks, and two or three drops to a pint will keep a sample fresh for two or three days. Benzoic, boric, and salicylic acids are also used for the preservation of potted meats and sausages, and in the curing of ham and bacon. Salicylic acid is sometimes added to jam as an antiseptic and preservative.

Queensland being a much hotter country than England, the more popular of these preservatives, principally borax and boric acid, are naturally used on a much larger scale, but no case of illness or indisposition caused by their use has yet been heard of, and it is considered that it would be very difficult to determine whether their addition is injurious or not (in the quantities used). It is held to be desirable that legislation should define the maximum amount of a preservative to be added, to prevent the possibility of an invalid or young child being given what might be medicinal doses.

Annatto, turmeric, saffron, and oil-soluble azo-aniline dyes are used for the colouring of butter and cheese. Those most popular are liquid annatto and oil-soluble anilines. A salt of copper, usually the sulphate, has been employed to render bottled fruits and vegetables a bright green colour. Cochineal, saffron, indigo, chlorophyll, and aniline dyes impart the various tints to articles of confectionery. Roseaniline, fuchsine, or magenta are used for jams and preserves. Turmeric and yellow aniline dyes bring up the colour of sugar. Red ferruginous earths, as bole Armenian, Venetian red, and Bismarck brown are occasionally added to sauces, sausages, and potted meats. Fuchsine, cochineal, logwood, beetroot, and alkanet have been detected in wines. Caramel or burnt sugar is very largely used for the colouring of spirits (brandy, rum, and whisky), and also for artificial vinegar.

Although the majority of the above colouring agents may be considered harmless, it will always be a question whether any may be present in sufficiently large quantities to be in any way injurious to the consumers' health. The non-poisonous colouring matters are some of the aniline dyes (*when pure and free from arsenic*), saffron, turmeric, annatto, chlorophyll, and generally any vegetable matter. In one or two cases of jam colouring the amount of roseaniline present has been sufficient to be decidedly injurious, especially as jam is an article largely consumed by children. With regard to vinegar it was, until recently, quite the exception to obtain a pure malt vinegar, the article usually sold being simply very dilute acetic acid, coloured with burnt sugar.

## (3) VICTORIA.

Law of 1890 as in Tasmanian Act of 1885 (*see later*).

Law as to sale of spurious butter as in Western Australia (*next below*).

The Secretary for Agriculture says boric acid forms the base—in some cases the whole—of the many-named preservatives used in food. During the first export seasons, 1889-90, most of the butter was exported without boric acid; but butter in which one-half per cent. of preservative was added kept better and was more palatable and fit for consumption, and realised up to £5 per ton more. Numerous experiments have been made during the past few years with a view of ascertaining if butter can be manufactured to stand

the variations of temperature and length of time without deterioration before reaching the British consumers. The system of pasteurisation has been adopted in many of the factories with this object, with encouraging results. So far, even the pasteurised butter to which a little boric acid has been added has been found to keep better than that without it.

Mutton, beef, rabbits, and other meats exported, being frozen, do not contain any preserving material. In the spring and early summer months little or no colouring is used in butter or cheese. In autumn up to five ounces of annatto seed and olive-flavoured cotton seed oil colouring is added to 100 gallons of cream containing 45 per cent. of butter, and in cheese up to an ounce per 100 gallons of milk.

Dr. Springthorpe, physician to the Melbourne Hospital, and lecturer on therapeutics, dietetics, and hygiene at the Melbourne University, states on the subject of using preservatives in food: "As regards boric acid, I have some absolute evidence within actual defined limits. I have now for some years treated practically all my hospital typhoid patients on a diet of sterilised hopped malt extract with very satisfactory results from every point of view, and a very large number of cases have been similarly treated in Victoria, Queensland, Western Australia, and New Zealand, with similar results. My routine treatment for over three years has been to add  $2\frac{1}{2}$  grains of boric acid to the ounce of sterilised water to every meal of malt, usually twelve in twenty-four hours—that is, 30 grains of boric acid in the day—with intent and result of keeping the malt aseptic throughout its assimilation. Some 300 patients have been under my personal observation, taking 30 grains of boric acid daily for periods varying from one to six or nine weeks, and I have never noted any bad effects; on the contrary, the local condition of the intestine recovered its normal tone. The patients convalesced, as a rule, stronger rather than weaker than patients on ordinary milk."

#### (4) WESTERN AUSTRALIA.

But little done so far, in the absence of legislation.

Preservatives and colouring matters believed to be used in food to a very slight extent.

The law of 1898, on the lines of the Tasmanian law of 1885 (*see later*). The sale of spurious butter "with or without salt or other preservative and . . . colouring matter" can only be carried on under a system of declaration.

#### BAHAMAS:—

No special local legislation. Practice does not obtain.

#### BARBADOS:—

Caramel (burnt sugar) is used for colouring rum, and cochineal or fuchsine in minute quantities for colouring sweetmeats made and sold in the colony. Careful enquiries failed to ascertain other instances of the use of preservatives or colouring matters in food of local manufacture.

#### BRITISH GUIANA:—

Law of 1892 prohibits the colouring or staining of food in a way to render it injurious to health (as in Article 1 of Malta law of 1888—*see later*).

Report by the Government Analyst says that both sugar and rum are artificially coloured. No preservatives are used in articles of food intended for export. The bulk of the sugar made is for export to the United States, and is not coloured. That sent to England is treated while in the vacuum pan with small quantities of a solution of stannous chloride (protochloride of tin, tin crystals, dyers' crystals) which results in the production of the yellow bloom characterised "Demerara crystals." The colour is really a modification of the natural colouring matter of the cane, and contains none of the stannous chloride. Investigations made many years ago proved that all but minute traces of the stannous chloride used pass into the residual molasses. Investigations made in England by Dr. Stevenson and other experts fully confirmed the results above mentioned, and further proved that the minute traces of tin retained by the sugar were physiologically inactive. A similar bloom or colour may be attained by the use of sulphuric acid, phosphoric acid,

and various vegetable acids in the vacuum pan, but the results are not satisfactory or lasting. Attempts have been made to use certain aniline dyes in the place of stannous chloride, but have proved failures, and no sugar so coloured has been exported from the colony for many years past.

Rum is coloured with caramel or burnt sugar or molasses. The colouring matter is quite uninjurious. Attempts have been made to use aniline dyes in the place of caramel, but have all failed, and no rum has been exported from the colony for some years past so coloured.

Practically, therefore, the colouring of food stuffs is limited to the colouring of sugar intended for the English market by a modified form of the colouring matter natural to the cane and to the colouring of rum by caramel. Of the chemical agents used in the manufacture and colouring of sugar only physiologically inactive traces remain in the product.

#### BRITISH HONDURAS:—

No special local legislation. Practice does not obtain.

#### CANADA:—

The law does not prevent the use of preservatives and colouring matters in food unless they are injurious to health.

Law briefly as follows:—

Law of 1886, as amended in 1898.—Food is adulterated if it contain any added poisonous ingredient, or any ingredient which may render it injurious to the health of a person consuming it, or if it so coloured or coated or polished or powdered that damage is concealed, or if it is made to appear better or of greater value than it really is.

As regards the addition of non-injurious matter to food, the law of 1898 says that food is not adulterated: "If any matter or ingredient not injurious to health has been added to the food or drug because it is required for the production or preparation thereof as an article of commerce, in a state fit for carriage or consumption and not fraudulently to increase the bulk, weight, or measure of the food or drug, or to conceal the inferior quality thereof, if each package, roll, parcel, or vessel containing every such article manufactured, sold, or exposed for sale is distinctly labelled as a mixture, in conspicuous character, forming an inseparable part of the general label, which shall also bear the name and address of the manufacturer."

As to penalties for injurious adulteration of articles, the same law says that if such adulteration is within the meaning of this Act deemed to be injurious to health, for a first offence a penalty not exceeding 200 dollars and costs shall be incurred, or three months' imprisonment, or both, and for each subsequent offence a penalty not exceeding 500 dollars and costs, or six months' imprisonment, or both, and not less than 50 dollars and costs.

As to vinegar, the law of 1886 says that vinegar sold, or offered, or exposed for sale, shall be deemed to be adulterated in a manner injurious to health if any mineral acid has been added thereto, or if it contain any soluble salt having copper or lead as the base thereof—whether such mineral acid or said is added either during the process of manufacture or subsequently.

As to liquors, it says that alcoholic, fermented, or other potable liquors sold, or offered, or exposed for sale, shall be deemed to have been adulterated in a manner injurious to health if they are found to contain any of the articles mentioned in the schedule to the Act, namely, cocculus indicus, chloride of sodium (otherwise common salt), copperas, opium, cayenne pepper, picric acid, salicylic acid, Indian hemp, strychnine, tobacco, darnel seed, extract of logwood, salts of zinc, copper or lead, alum, methyl alcohol and its derivatives, amyl alcohol, and any extract or compound of any of the above ingredients.

A form of warranty has also been enacted (in 1898) to the effect that articles manufactured by the vendor or by persons known to him are pure and unadulterated within the meaning of the Adulteration Act.

In actual practice it has been found that salicylic acid has been found in beer, condensed milk, and preserves, and borax in milk. Only salt used in butter. British

Appendix. Importers have urged the use of preservatives, but Canadian manufacturers have not fallen into the practice. Annatto is used for colouring butter and cheese, but only in very minute quantities in cheese. Many baking powders also contain alum, and none of these have been declared by the Courts illegal. Salt only is used in curing bacon, which is sprinkled with borax when dry, for purposes of transit. No preservatives used in preserved fruits and jams. The Department of Inland Revenue at Ottawa is of opinion that salicylic acid in beers, etc., is injurious to health, and that alum in baking powders is not less so, but as yet the Courts have not determined the point.

#### CAPE OF GOOD HOPE:—

As regards butter, the addition of preservatives is seldom resorted to except in a few instances when butter is made for keeping purposes. In this case preservatives are usually added at the rate of 1 lb. to 100 lbs. of butter, the chief ingredient in the preservative being boracic acid. Colouring matter is as a rule only used in cheese making, and is added at the rate of 2 fluid ounces to every 100 gallons of milk. The colouring matter is generally a vegetable product and entirely harmless.

As regards wine, the only preservative generally and openly used in this Colony is alcohol in the form of spirits of wine, the maximum strength to which wines are thus fortified being 35 per cent. proof spirit. Other preservatives, if used to any extent, are applied secretly, and the only substance known of as being used in this manner is salicylic acid, which is added at the rate of 3 to 5 ounces per hogshead of 64 gallons.

With regard to butter, colouring matter is sometimes added, but it is doubted whether the practice of adding a preservative is in any extensive use.

It is very seldom necessary to use colouring matter in wine, the blending of different wines being resorted to to obtain the desired result. In the few cases where colouring matter is applied, the substance generally used—in small quantities, according to the depth of the colour required—is caramel. But colouring matter is frequently added to the red wines. Some time ago an attempt was made by a gentleman to induce the Government to adopt at the Government Wine Farm and to advocate the use by wine farmers of a certain preparation to be added to new-made wines. This preparation was found upon analysis to contain a considerable quantity of formaldehyde, upon which chemical the results obtained by the use of the preparation really depended, its effect being to arrest further fermentation, and therefore to ensure the keeping of the wine. Its use was reported against, and the preparation was therefore not taken up by the Government.

The use of formalin was also reported against in wines on the ground (a) that there is no definite knowledge of the action on the human system of the continuous consumption of formaldehyde, and (b) that physiologically the continuous use of a powerful disinfectant and irritant would injuriously affect the act of digestion, especially that portion of it dependent upon bacterial action.

Tumeric has been frequently found in mustard, and aniline colours at rare intervals in sugar; and bottled fruit from Australia has contained sulphurous acid.

Law of 1890 as in Tasmanian Act of 1885, but one clause says that if any person selling, offering, exposing, or keeping for sale any spirits, wine, malt, or other liquor, shall have upon his premises, or in his possession any vitriol cocculus indicus, nux vomica, tobacco or tobacco juice, pepper, chillies, opium, aloes, salts of zinc or lead, copperas, faba amara, logwood, or any extract or preparation thereof respectively, or any other poisonous or deleterious substance whatsoever, otherwise than for some innocent purpose, the proof of which shall lie on such person, he shall be liable to the penalties.

#### CEYLON:—

The only law at all touching the subject of preservatives is one clause of the Penal Code having reference to the sale of food or drink in a noxious or unfit state.

Materials known to be used in the Colony for preserving food are:—

- Salt (chloride of sodium), for meat and fish.
- Saltpetre (nitrate of potash), for meat.
- Vinegar (acetum), for meat and fish.

"Hal" Bark (*Vateria acuminata*), to preserve "Toddy" from acid fermentation.

Boracic acid, for preserving milk and butter.

"Goraka" (*Garcinia cambogia*) pericarp, used for preserving fish and also meat.

Tamarind (*Tamarindus Indica*) pulp, for preserving fish.

Cinnamon (*Cinnamum zeylanicum*), to prevent acid fermentation in preserves.

Pepper (*Piper nigrum*), to prevent fermentation in pickles. It is also used to preserve honey.

"Arrack" (Palm spirits), for preserving curried meat.

Lime and the bark of *Vatruia Indica* to retard fermentation when preparing jaggery from toddy.

The foregoing are the chief substances used for preserving food, and their use in any quantity whatever is not injurious to health.

The following are also used, though not so largely:—

Honey, for raw meat.

Glacialine, a preparation imported from England for meat. It is believed to contain borax in some form.

Cow ghee, for meat.

Materials known to be used for colouring food are:—

"Shoe Flower" (*Hibiscus Rosa-sinensis*), red, for colouring preserves and sweets.

Annatto (*Bixa Orellana*), orange yellow, for butter.

Sapan (*Caesalpinia Sapan*), red, for colouring boiled eggs and sweets.

Cochineal (*Coccus Indicus*), pink, for sweets, puddings, etc.

Spinach (*Casella Alba*), green, for sweets.

Turmeric (*Curcuma Longa*), yellow, for colouring rice and roasted gram.

Burnt sugar for colouring home-made wines.

The use of these materials in any quantity whatever is not injurious to health.

The following substances are also used:—

Magenta, which is considered poisonous in very small quantities for the preparation of sherbet.

Kolichayam, a chemical preparation commonly believed to contain arsenic. It is sold in small paper boxes, and consists of small grains—red, pink, and green in colour.

#### CYPRUS:—

No special local legislation. No preservative used other than salt.

#### FALKLAND ISLANDS:—

No food preservatives.

The "law of England" so far as applies to local circumstances is in force.

#### FIJI, GIBRALTAR, GOLD COAST:—

No special local legislation. Practice does not obtain.

#### HONG KONG:—

No preservatives other than common salt found, though sought for, and no colouring matters found, save caramel and magenta to a small extent in beverages. A certificate of adulteration would be given by the Government Analyst were a food such as cayenne pepper or mustard to be artificially coloured, or were a food to contain a preservative such as borax, boracic acid, and such like chemical substances, and there is but little doubt that on such a certificate the seller of the adulterated food would be convicted.

#### JAMAICA:—

Law of 1898 as in Malta, Art. I. of 1888. Local practice of use of preservatives and colouring matters wholly inappreciable in extent, and injurious ingredients do not appear to be used.

#### LAGOS:—

No special local legislation.

**LEEWARD ISLANDS :—**

No law in force. No attention has been given to the matter. Practically no use of preservatives or colouring matters, save alleged use of sulphate of copper at times in a domestic preparation of preserved lime peel.

**MALTA :—**

Law of 1859.—Art 1.—Food and drinks exposed for sale, may be seized for analysis as to admixtures of a kind injurious to health, under certain specified methods of procedure.

Art. 4.—If mixtures injurious to health are found, sentence shall follow. If not, payment for any damage sustained shall be made.

Law of 1888.—Art. 1.—Punishment by imprisonment to follow on sale of drinks or food mixed with substances to render them injurious to health, unless the vendor were ignorant of the mixture, and could not reasonably have been expected to know. In all cases the food, etc., is to be forfeited.

Art. 2.—Food and drinks in a state of decomposition injurious to health shall not be sold.

Law of 1893.—Art. 1.—The importation of food and drinks which might be injurious to health may be prohibited.

**MAURITIUS :—**

No preservative known. Only colouring known is one called locally "Golden Bloom," but rarely used, and not regarded as deleterious, but never analysed by the Government.

Penalty lies on sale of liquor containing any ingredient hurtful to health, under laws of 1838, 1869, and 1878.

**NATAL :—**

Law of 1898.—Byelaws, enforceable under penalties for contravention, may be made by town councils in regard of food containing a mixture, colouring, or powdering of injurious ingredients, so as to render the article injurious to health, and may prohibit the sale of any such food if the fact be not declared.

No reports under the Act have been made, as only two boroughs have at present (October, 1899) framed bye-laws.

**NEWFOUNDLAND :—**

No special local legislation. Practice does not obtain.

**NEW ZEALAND :—**

The law of 1898 stipulates as follows:—No person shall: (1) Mix with or add to dairy produce, or use in the manufacture thereof, any extraneous ingredient of any description; nor (2) Manufacture any dairy produce from other than milk or cream; nor (3) Knowingly sell any such produce. Provided that, except in so far as is otherwise provided by regulations under this Act, nothing in this section contained shall be construed to prevent pure sugar, common salt, or any harmless coagulative, preservative, or colouring ingredient or constituent being used in the manufacture of dairy produce.

The Governor may from time to time, by Order in Council gazetted, make regulations consistent with the provisions of this Act, for preventing or limiting the use of preservatives or other ingredients in the manufacture of dairy produce.

It is the practice among cheese manufacturers in New Zealand to use at times a small quantity of a solution of annatto (1oz. to 100gals. of milk) for the purpose of colouring the cheese. It is the same material as that which is used by cheese makers in all countries. New Zealand cheese is free from preservatives of any kind. The butter manufacturers occasionally put some colouring matter in their butter, employing for the purpose the same substance as is used in cheese making, prepared in a different manner, but quite as harmless.

Preservatives, known by such trade names as "Preservative," "Preservitas," etc., are used at some of the butter factories to the extent of  $\frac{1}{8}$  to  $\frac{1}{4}$  of a lb. to 100lbs. of butter.

It is forbidden to sell milk that has not been properly cooled immediately after having been drawn. And no person shall sell other than "pure milk" without declaration, "pure milk" being milk which does not

contain "any preservative of chemical or colouring matter of any kind whatsoever." Appendix.

**NIGER COAST PROTECTORATE :—**

No special local legislation.

**ST. HELENA :—**

No trade in which colouring matters are used.

**ST. VINCENT :—**

No special local legislation.

**SEYCHELLES, SIERRA LEONE :—**

No special local legislation. Practice does not obtain.

**STRAITS SETTLEMENTS :—**

No law in force. Only exported food is tinned fruits, placed in flavouring syrups. No preservative or colouring matter is added.

Chinese and other nations use a dark red dye imported from China for colouring cakes, and extract from certain leaves a deep green dye for cakes and sweetmeats. Both are said to be harmless. Cooks often use the flower of the hibiscus to give a red colouring to syrups and sauces, an artifice said to be harmless. There is no reason to believe that the use of injurious preservatives or colouring matters prevails to any extent.

**TASMANIA :—**

The practice has been to order proceedings to be taken in all cases where the Government analyst reports that the matters used are in themselves deleterious or are present in quantities injurious to health. Where the matters are innocuous, and only reduce the commercial value of the article adulterated, the Board leaves it to the persons prejudiced to take action.

The law of 1885 renders penal, except in cases of proved absence of knowledge which could reasonably have been obtained, the mixing, colouring, or powdering of food with any ingredient or material so as to render the article injurious to health; but declaration by label of the addition of non-injurious material protects the vendor, and the addition of non-injurious substances necessary to the preparation of an article in a fit state for carriage is allowed, if they do not fraudulently conceal inferiority of quality.

**TRINIDAD :—**

Law of 1881 forbids sale of intoxicating liquors mixed with, or storage on licensed premises in the absence of satisfactory reason of, cocculus indicus, chloride of sodium, copperas, salts of zinc or lead, alum, sulphuric acid, or any extract or compound of any of these articles, which may be added to by Order.

Law of 1895 as in Malta, Art. I. of 1888. (See *Ante*.) Preserved peas used to have 3 grains of copper per lb. Proceedings eight years ago led to reduction of quantity added to from  $\frac{1}{4}$  to 1 grain per lb.

Wines of low alcoholic strength sometimes contain small proportions of salicylic acid.

Butter is coloured with annatto, and some, principally French, contains 27 per cent. of salt.

(All the above are imported goods.)

Locally, milk contains no preservative, and rum is coloured with caramel solution.

Recently proceedings have ceased in view of the difficulty of proving that preservatives as used are injurious at a single meal.

**WINDWARD ISLANDS :—****(1) ST. LUCIA.**

No law deemed necessary. Only sugar is coloured with a matter commercially known as "bloomer" for sugar called "yellow crystals," and then only in amount not considered likely to be injurious to health.

**(2) GRENADA.**

No law in force.

Only substances used are annatto (milk and sweetmeats), prickly pear (sweetmeats), and burnt sugar (new rum). None of these regarded as injurious to health.

## Appendix.

## APPENDIX No. III.

## REPORT on Visit paid to AMSTERDAM, HAMBURG, and DENMARK in relation to the use of Chemical Preservatives in Milk and Butter.

When the Food Preservatives Committee had been taking evidence for some few months, it became increasingly apparent that a visit to Denmark, as a great butter-exporting country, wherein the use of certain chemical preservatives was prohibited, and to Ireland, as a butter-producing country, wherein such preservatives were largely employed, would be desirable before the verdict of the Committee was arrived at. It was finally decided that such visits should be made, and it was deemed important that the heat of summer should be chosen as best suited to a correct estimation of the difficulties to be met in the manipulation, storage, and transport of butter unaided by chemical ingredients of a specially preservative character. It was the more desirable to examine the Danish methods, owing to the fact that some useful information might, it was thought, be obtained with regard to the milk supply, the use of chemical preservatives in milk being prohibited in that country, and pasteurisation being at times resorted to.

Accordingly August and September were arranged for, the first for the Danish visit, and the second for the visit to Ireland. Unfortunately, the engagements of the Committee were such as precluded the presence of the chairman and other two of their number in Denmark, and hence we alone were in a position to proceed; but in view of the importance of heat as a factor in the programme set forth, it was decided that we should carry out the original scheme. It is satisfactory to be able to record that the weather throughout our stay on the Continent was hot and dry.

In addition to the facts which we chronicle in this report, we obtained certain information on matters other than milk and butter supplies, but of too piecemeal a character to warrant our setting it forth, touching as it does on the bacon industry, the egg and fish trades, the general question of preservatives in food, and such other subjects as the slaughtering of cattle and swine, and the transport of meat. Our time was far too restricted to admit of anything approaching a grasp of the numerous points of interest on matters analogous to our specific subjects, and hence, while we were glad to learn what we could, we cannot pretend to the same intimacy with these other questions as with those dealt with in the succeeding pages.

Before proceeding to the Continent we secured the assistance of the Foreign Office in the direction of special passports and introductions, and from Mr. Harald Faber, F.C.S., the Commissioner of the Agricultural Department of the Danish Government in London, who had already tendered evidence before the Committee, we obtained a number of valuable introductions, including the following, viz.:—

Hr. L. E. WULFF, Chief of the Department of the Ministry of Agriculture.

Prof. V. STORCH, Director of the Royal Laboratory for Agricultural Research.

Hr. B. BOGGILD, consulting dairy expert to the Royal Agricultural Society of Denmark.

The three leading milk companies in Copenhagen, viz.:—

"Copenhagen Milk Supply" (Director, Hr. G. Busck).

"The Milk Supply Pasteur" (Director, Hr. E. Krohn); and

"Det danske Maelke Compagni," System Cassé (Director, Hr. Salicath).

The Hon Alan Johnstone, H.M. Ambassador at Copenhagen, was unfortunately absent in England, at the date of our visit, but from Captain Boyle and Mr. C. Holger Funch, of H.M. Consulate, we obtained much help, as from all who are named in the above list, and many others who find mention in this report. We were, indeed, most kindly received on all sides, and no little time and trouble were taken to furnish us with the fullest information available.

Nor does this apply to Denmark only, but also to Amsterdam and Hamburg, at each of which cities we

spent a day on our outward route, and learnt something of the milk supplies of both.

In what follows we do little more than reproduce the notes which were taken at the time as to that which we saw and were told, deeming it best to limit ourselves thus rather than to comment on or attempt to criticise all of the numerous phases of trade and practice coming beneath our notice.

## AMSTERDAM.

We had the misfortune to visit Amsterdam during the absence of Dr. Ringeling, the Health Officer of the City, but we were happy in finding in his place Dr. J. W. Jenny Weigerman, the Assistant Health Officer, to whose great kindness we owe all that we have learned respecting the milk supply of the city and the subject of the chemical preservation of food. To the Mayor and the members of the Municipality we are also greatly indebted for the kind hospitality extended to us in our inquiry.

In addition to Dr. Jenny Weigerman, we were afforded an opportunity of conference with Dr. Reicher, the City Analyst, and with the Director of the Fabriek voor Gesteriliseerde Melk, Amsterdam, from whom we obtained much useful and interesting information.

As is well known, Amsterdam, a city of over half-a-million people, is situate on the IJ, one of the ramifications of the Zuider Zee, while the River Amstel, which is here navigable, passes through the middle of the town on its way to the IJ. The city is for the greater part surrounded by pasture land, which affords good grazing for milch cattle.

The milk supply to the city may be broadly divided into three sections, namely:—

- (1.) Pasteurised milk.
- (2.) Sterilised milk.
- (3.) Raw milk.

But before proceeding to speak of these supplies we may perhaps make brief reference to the law, and to the facts forthcoming, as to the use of preservatives in food.

The current law enacts that vendors of foods, drinks, or drugs, who, knowing them to be "falsified," shall sell them without declaration as to their actual nature, shall be liable to three years' imprisonment.

As a routine precaution, and apart from special analyses, the milk supplies of the city are tested twice in each year, though we did not learn that the samples of each source are examined for added chemical preservatives. Milk has, however, in the past been analysed *quâ* such admixtures, for boracic acid, formaldehyde, salicylic acid, benzoic acid, and fluoride of sodium, and as a matter of fact boracic acid has never been found in milk supplied to the city. Indeed, on only two occasions has a chemical preservative been detected, butter-milk alone being then in question, and formaldehyde the preserving agent.

It may be added that no chemical preservatives other than salt have ever been found in butter analysed in the city.

As regards the sterilisation and pasteurisation of milk, we were enabled to see something of the actual operations of the Fabriek voor Gesteriliseerde Melk "Amsterdam."

This establishment has laid down conditions on fulfilment of which alone milk will be received from the farmers who contract to send in their produce. Thus the milk sent must be from cows owned by the contractors; it must be pure, unadulterated, uncreamed, sweet to taste, and in other ways up to a certain standard. The evening milk that comes directly to the establishment must be cooled (milking is at 2 a.m. and 2 p.m.), and screened at the farm. The udders of the cows must be cleansed immediately prior to the operation of milking, and the milk of cows milked in the stalls in winter must be forthwith taken from

the sheds to a cool chamber. All milk must be similar in constitution to the sample taken in the presence of the farmer by the director for examination by the analyst of the establishment. The results of such examinations are to be final both as to such sample, and as to those taken each day from one and another farm's supply for purposes of testing. The milk of every newly-added cow at a farm must be analysed by the same expert before her milk can be accepted. Milk from such cows must be sent in separately; it is paid for, but not used. The veterinary surgeon employed by the firm has power to veto any milk supply. Notification of infectious disease at a contracting farm is compulsory, but the exact reason for this is not at once apparent, since milk for an infected farm would, we gathered, be used, owing to the fact that no danger to the public health could arise in consequence of the pasteurisation or sterilisation of all milk received.

On receipt at the premises in Amsterdam the milk is at once screened, and then raised to a temperature of 30deg. C. (86deg. F.), in order to facilitate the centrifugalising process which follows. The milk and cream thus separated are then brought together again and intimately mixed by a series of revolving rollers. In the process of centrifugalising there is left behind on the inside of the separator the usual residue, which consists of a viscous-looking mass of a slimy, objectionable appearance. It contains much debris such as hair, inorganic mud, and other substances which have not been arrested in the preliminary strainings; indeed, separation may be rightly regarded as possessing very material cleansing properties. The residue, however, consists mainly of caseous matter, and, as has been experimentally demonstrated, it contains numerous bacteria.\*

After re-mixing the separated milk and cream, the whole milk is pasteurised, i.e., it is led into litres (1·76 pint) bottles and raised during a period of twenty minutes, to 75deg. C. (167deg. F.), at which temperature it is left for the space of half an hour. The milk is then, with a view to destroy any approach to a "cooked" flavour which might otherwise result, at once cooled down to and kept at 11deg. C. (52deg. F.), until sent out.

All separated milk sold as such is also pasteurised in the same way, and it is said to be much sought after by the poorer classes. Some of it goes back to farmers for the feeding of calves.

Pasteurisation has been practised in the city during the last ten years, and in Dr. Jenny Weigerman's opinion much reduction in the infantile mortality of Amsterdam has thereby resulted. Moreover, milk-borne outbreaks of enteric fever are now less frequent than heretofore, a result Dr. Weigerman attributes to pasteurisation rather than to other sanitary improvements, the Health Department having been at pains to exclude other possible factors in arriving at this conclusion. Children take kindly to the milk, that intended for their use being put up in bottles in quantities sufficing only for one meal; thus ensuring clean receptacles at each time of feeding; in fact, the operations now in question bear some relation to those of the "Goutte de lait" Society which has for some time been at work in certain parts of France, and which claims to have brought about a material reduction in the infantile mortality of the localities concerned. The Health Department were unable to state the proportion of the population consuming pasteurised milk; but the director of the Fabriek "Amsterdam" estimates that three-fourths of the total population are taking milk that is either pasteurised or sterilised, his firm alone selling three bottles of the first to each one of the latter for town consumption. The firm sends out 6,000 pints (in 3,000 quart bottles) daily, exclusive of milk exported in a sterilised condition for purposes of shipping companies and the like.

Milk about to be sterilised is, after being placed into open bottles, transferred to an autoclave containing cold water, the temperature of which is gradually raised by means of steam to 90deg. C., the air contained in the bottles being thereby expelled. At this point the glass rubbed-banded stoppers are firmly pressed home by a strong wire attachment, the lid of the autoclave is

screwed down, and the contained water raised to and kept at 105deg. C. (221deg. F.) for twenty minutes. The milk is then cooled down to 40deg. C. (105deg. F.). Cold water is next let into the previously emptied autoclave, and the temperature of the milk finally reduced to 11deg. C. (52deg. F.), before being sent out in the ordinary way to the city, or exported.

We saw some sterilised milk which was bottled in 1884, and which it was declared was still good. It is not, of course, claimed for such milk that it will keep any longer than ordinary sweet milk when once a bottle has been opened.

No medical objection has been raised to the use of sterilised milk in Amsterdam. Indeed, the medical faculty have shown approval of its use. Much sterilised milk is issued to steamship companies, and keeps sound during voyages of three-and-a-half months' duration, even when the Equator is crossed and recrossed.

Great attention is paid to the cleansing of utensils at the establishment in question. The farmers' cans are cleansed in water heated by the injection of steam, each farmer having his own cans, which are always returned to him. He is forbidden to do anything with the cans himself in the way of cleansing.\* The vessels used in the establishment are treated in similar fashion, and the milk bottles returned by customers for refilling are cleansed with warm water, by revolving brushes applied to the interior, and finally by steam injected into the inverted bottles. The rubber bands of the stoppers are sterilised separately (one customer gets milk with ordinary corks to the bottles by his own desire).

There are in the city thirteen firms which distribute only pasteurised milk; but there is also a considerable amount of milk sold in a raw state by small vendors. We were, however, much struck by the large extent to which pasteurised and sterilised milk was exposed for sale in Amsterdam, even in the poorest parts of the city.

As illustrative of the hold which such methods of treating milk have obtained in the city, it may be mentioned that we saw one little shop in quite a poor quarter with a notice in the window to the effect that the milk there sold was "free from bacteria."

The Copenhagen system of treating milk by cooling, filtration, and bottling only ("Busck" method) was stated to have failed, financially speaking, in Amsterdam. We learned no particulars of the experiment.

Milk reaches the city by road or by water, from both sides of the River Amstel. It is sent in at once after being drawn, some of it coming a journey of two hours by road. One large firm had to discontinue bringing milk into the city by road for distribution after simply cooling it, owing, it is said, to the liability of the milk to become partly churned, and hence not available for distribution.

Delivery of milk is made twice daily to houses. It is seventeen hours old when first sent out from the Fabriek "Amsterdam."

No great outlay had been incurred in establishment expenses at the Fabriek "Amsterdam." The whole premises were scrupulously clean, and the floors cemented. The workpeople nearly all wear wooden shoes, the floors being here (as in almost all such premises seen elsewhere) running with water, alike in receiving, heating, cooling, bottling, and cleaning chambers.

Pasteurised cream is exported by the firm for American lines of steamships, etc. No clotted cream is made. Fresh cream is supplied to the city, without the use of any chemical preservatives. Cream intended for the manufacture of butter for immediate consumption is not pasteurised. All cream used for making export butter is, however, pasteurised.

The price for pasteurised and sterilised milk is 10 cents (2d.) per litre (·76 pint) bottle; the ordinary raw milk sold by the farmers and small vendors (not in bottle) is 8 cents per litre. Customers of the pasteurised milk pay 3d. for the use of the bottles pending their return, but this really affects only chance customers, since, having once paid for a bottle, householders regularly supplied are liable to no further charges in this respect, empty bottles being collected as a routine matter when filled ones are delivered.

\* Slime such as is here in question has been found crowded with tubercle bacilli, and in Denmark and in some other countries, with the view of limiting the spread of tuberculosis, such slime is ordered to be burned to prevent pigs from being fed thereon.

\* As a general rule, and apart from the usage of this establishment, the big farms sterilise their own churns, but this is not the case in the small farms. It may be said in this connexion that the water supply of many farms is still regarded as bad by the Health Department.

## Appendix

The firm named could, they informed us, export sterilised milk to London, including charge for freightage, delivery in London, cost of bottles, and return of empties, at an inclusive cost much below that now paid by consumers of sterilised milk sent out by London dairymen.

It was abundantly evident to us that much attention has been given to the question of the milk supply of Amsterdam alike by the Municipal Health Authorities and the leading firms. It would seem to be but a matter of time, and that a brief one, for the supply of the city to be brought into the hands of such firms in its entirety, unless smaller vendors adopt methods akin to those now in vogue in the thirteen establishments to which we have referred. We were much struck by the small compass within which the Fabriek "Amsterdam" carries on its daily work, and which, in our estimation, makes it practicable for any small co-operation of milk vendors, under circumstances such as obtain in Amsterdam, to set up a plant of a like character with very fair return for capital outlaid. So far as we could learn, all firms of the sort here described are paying well, and, since the trade in such treated milk is growing, it would seem feasible to expect that not long hence Amsterdam will be a large city practically supplied with pasteurised (or sterilised) milk alone. Any difficulty which may lie in the way of furnishing such minute quantities of milk as are purchased by the extremely poor could perhaps be met by some method of distribution apart from bottles, which would enable very small quantities of treated milk to be sold over the counter in the same way as now obtains.

## HAMBURG.

As our route from England to Denmark took us by way of Hamburg, a state of some 700,000 population, we were glad to have the opportunity, which was kindly afforded us by Dr. Reincke, the State Health Officer, of discussing with him the question of food preservation and colouring in the city. Not only did Dr. Reincke place himself at our disposal, but he also introduced us to the expert officers in the Municipal Laboratories, who were good enough to afford us much useful information as to the extent to which preservatives and colouring matters were detected in Hamburg by laboratory research.

There is at present no State control of farms or farm produce outside the city boundary. In the city itself there is a central office charged with the supervision of all kinds of food, and its officers have powers of entry on business premises. As regards farms beyond the city limits, the municipal authorities hope soon to bring about a form of voluntary control of the dairying operations, farmers in a large and increasing number of instances having expressed their willingness to abide by the city bye-laws and regulations, and thus to secure registration as suppliers of dairy produce under veterinary inspection by the State. In the city, the owner of a dairy or of a milk shop is obliged to notify the occurrence of sickness in his family or among his servants, and persons themselves ill with infectious disease, or having been in contact with infection, are not permitted to take any part in the handling of milk. In the case of a shop, its closure is the alternative to removal of the patient to hospital. As to cow owners in the city, it is laid down that they must ensure cleanliness of the hands of milkers and of the udders of cows. The sheds must be provided with good drainage arrangements, and milk cans must be cleansed with boiling water. The whole milk traffic of the city is under control by a State veterinary surgeon, but there is no compulsory examination of cows on account of tuberculosis.

The city has not been without reminders of the need for attention to its milk service, since several outbreaks of enteric fever have been traced to the agency of milk during the past few years. Three years ago fifty cases were found to have their source in the milk of one vendor.

The farms on the marshes around Hamburg are not well supplied with water, and it is feared that dairying utensils may be washed at times with indifferent water. In general, the farms derive their supply from the river, there being much iron in the marsh water.

Good pasture is common on the marshes close at hand, though but few cows are to be found on such marsh land as is actually within the city boundary. Milk, which is delivered twice daily, comes into the town by rail and river as well as by road. There are no special railway waggons for the short distances that milk travels by rail. The German railroad stations have no raised platforms, and hence large churns such as are common in England would be difficult to deal with. Fifteen German miles

(sixty-nine English) is the maximum distance which milk travels to Hamburg, and this is performed by water or by rail. The general facilities as to proximity and transit are such that milk is only twelve hours old when delivered to houses in the city.

Milk is much watered in the town, and of each average 100 samples which are found to be unsatisfactory, 24 are watered, the amount of dilution being from 10 to 14 per cent. of added water.

The law (Hamburg Mark Law) in force in the State forbids the sale of milk mixed with water or any other foreign matter, including all kinds of preservatives. The detection of preservatives leads to the punishment of the vendor. As a matter of fact, preservatives are seldom found in milk. The law against them was enacted in 1894. Prior to that date milk was not examined for preservatives, but the effects of the enactment in question may be judged from the fact that in 1895 as many as 23 per cent. of samples examined contained boracic acid, in 1896 14.5 per cent., while in 1897, of 2,422 samples tested, 118 (less than 5 per cent.) yielded boracic acid, the preservatives being used mainly from June to September, and the skimmed milk samples being those most commonly preserved. Occasionally now, in summer, 22 per cent. of tested samples are boracised, but in the winter months only 1 to 3 per cent. Formerly from 2 to 3 per cent. of samples contained formaldehyde, now none is detected. Milk is not now examined as a matter of routine for benzoic acid or salicylic acid, but these chemicals were never found in the past. Preservatives are not used at the farms, but only by the middlemen, and it is thought that the use of preservative milk is not confined to any one class of the population. The Hamburg law affects only the State of that name. Regulations vary considerably in the different states and towns of the German Empire.

As regards butter, boracic acid has only been found on two occasions in samples examined in the laboratories. On both instances the article was blended butter. Probably the preservative had been added in Hamburg. Some 1,000 to 1,500 samples of butter are annually examined, though not all of them for preservatives. There is no law affecting the chemical preservation of imported butter.

Margarine samples are preservative to the extent of some 50 per cent. of their number, the addition consisting of from one to three per cent. of borax and boracic acid. Such addition is not an offence against the law. The preservative can, it is alleged, be tasted when present to the extent of 3 per cent.

Generally, the use of preservatives, save for milk, is thought to be increasing in the city. No definite pronouncement as to their harmfulness has been made by the medical faculty; but there is a consensus of opinion that they should be prohibited.

The cooling of milk is largely practised by farmers, good ice being cheap. Pasteurising of milk intended for butter-making, as well as that for consumption, is carried out by some farmers, and the milk again cooled down. These farmers are all outside the city limits and control, but they are becoming increasingly numerous, and the pasteurisation or sterilisation of all milk is said to be growing in favour with them.

In the city itself, the extent to which milk is pasteurised or sterilised is small. There is no general objection to the use of sterilised milk in Hamburg by the medical profession; but some medical men think that children fed on such milk have not thrived as well as children fed on raw milk. Dr. Reincke when in private practice shared this impression.

Most of the milk sold in the city is in a raw state; although boiled milk can be had if asked for at cafés, restaurants, hotels, etc. The greater part of the population boil the milk received into their houses; especially has this practice become general since the cholera epidemic of 1892.

Pasteurisation of milk is not regarded by Dr. Reincke as essential to a good milk service for Hamburg. He deems the "Busck" system at Copenhagen to be preferable.

No law has yet been enacted in the State on the subject of colouring matters in food. No arsenical colours are used.

## DENMARK.

## DANISH CO-OPERATIVE DAIRY SYSTEM.

Denmark is a country of co-operative dairy societies, there being at least three hundred such as the one at Haslev, which we describe later. The country has laid

itself out to perfect its butter manufacture, as a national industry, and the local exhibitions held all over the State in furtherance of the butter trade are aided by the Government. No State aid is, however, afforded to small farmers in need of capital for outlay on their business, but money can be borrowed at a low rate of interest from local banks, some of which belong to large co-operative societies. The central creameries draw milk from an average radius of six miles, and the farmers (who are members of the society to whose creamery they send their produce) are paid according to the amount and the quality of the milk sent in. Government inspectors are employed to take samples of separated milk on its way from the creamery to the farm for cattle food, in order to ascertain that the law which requires that all milk used as food for cattle shall be duly pasteurised has been carried out.

In the island of Zealand there are 400 parishes under local government, and nearly all possess regulations affecting the conduct of the dairying industry.

Hr. Boggild, consulting expert to the Royal Agricultural Society of Denmark, was good enough to give us his views on the subjects of butter manufacture and storage. He is of opinion that some 50 per cent. of the added salt is lost in the processes of working\* (an opinion in which Professor Storch, Director of the Royal Laboratory for Agricultural Research, concurs), and he believes that 90 per cent. can be thus expressed. The salt used does not, in his view, much aid the keeping properties of butter, though the retention of 3, and still more so of 5, per cent. would not be without some influence in this direction. Twenty years ago salt was used as a preservative, but from 10-15 per cent. was then added. Nowadays dealers add salt to suit particular local demands, and a large amount of that added is lost in the second working. Professor Storch thinks that with the methods now in vogue some 1·8 to 2·5 per cent. of salt remains in the finished article. The butter-milk running from the salted article is too salt for use by cattle, but the milk from the earlier (unsalted) working is good for food. There is no difficulty in sending absolutely fresh butter to England since it will keep many days, say a week, and still retain its quality. For the keeping of butter in Denmark there are in many places store-houses having ice holds beneath them, in order to cool the air. Hr. Boggild states that butter leaving Denmark contains from 12-15 per cent. of water.

As regards milk, he thinks ice is necessary to the supply of large towns if delivery be only once daily, but not so if milk be sent in twice a day, and is cooled down immediately after milking, scrupulous cleanliness being also, of course, observed. Nor is it necessary to cool evening milk if it be dispatched at once by rail for a journey of not more than two or three hours, provided such milk is always strained at the farms. Where ice is used, it is common to have a store-house large enough to admit of two years' supply, so that the occurrence of a single mild winter now and again will not place the dealer or manufacturer in difficulties. Some farmers store snow, but it is not easy to do so.

Hr. Boggild looks upon the English churns as better suited for transport of milk than the smaller cans used in Denmark; but the absence of platforms at railway stations forbids their use in that country on account of their great weight and the consequent difficulty of manipulation. He thinks the cans now generally used in Denmark are admirably adapted for purposes of cleansing, as there are no sharp or hidden angles, every part of the can being visible and accessible from the mouth.

Lime water, hot or cold, he judges to be best for use in the cleansing of milk cans, etc. All such cleansing is supposed to be completed with water that has been boiled.

Some butter, if it just misses the Thursday boats, may be a week old on leaving Copenhagen for this country. Its average age in four days when put on the Scotch markets. Professor Storch states that though some butter is sent to England quite fresh, the quantity is not great.

#### MARGARINE.

Butter fat to the extent of 10 per cent. only is allowed in margarine. The public can tell the difference between butter and margarine by the colour laid down by law, and the margarine can be sold only when made up in special shape and labelled. Its sale as butter renders the vendor liable to penalty.

\* This view is largely shared by all dairy experts (see the "Book of the Dairy" by Professor Fleischmann).

#### SANITARY STATE OF FARMS.

Most local authorities have framed regulations under the law of March 28th, 1808, forbidding the accumulation of dung in the vicinity of farm wells. Local regulations provide for the protection of private or public pumps against damage, and all drainage from the dung heap and stables must be prevented from reaching the water supply. The farm drains must remove all liquid filth, and pumps must be covered and protected against access of surface water. The immediate surroundings of all pumps must be raised above the level of the adjacent ground.

Professor Schou, of the Ministry of Agriculture, and one of the Government District Dairy Inspectors, was kind enough to accompany us and to afford us much valuable assistance in a visit to some dairy farms in the neighbourhood of Jyngby and Holte, some little distance north of Copenhagen, and we herewith furnish our notes relative to three of the farms visited.

(1) A cowshed at a small farm has three doors and two small windows. It has a cobbled floor, except in rear of cows' standings. Spaces are allotted so as to stall 14 cows, and the dimensions are 30ft. by 15ft. by 10ft. high, yielding 320 cubic feet per cow. But only one cow is now kept, her produce being used on the premises; the storage of ice is not considered necessary.

(2) A cowshed at a small farm, having no through ventilation, but aerial communication of cowhouse, stables, and pigery. Spaces allocated for 20 cows, and dimensions of shed 60ft. by 16ft. by 11ft. high, giving 545 cubic feet per cow. But only two cows are kept; their milk is all used at the farm, and no icehouse has been erected. The shed is whitewashed once a year.

(3) A larger dairy farm, typical, we were told, of many in the country, though many others are inferior. The cowshed is well designed, for 38 cows, and is 77ft. by 33ft. by 13ft. high, affording 870 cubic feet per cow. But only 32 cows are kept. It has six windows in the roof, all opening well; two doors at one end, and one large door at the other end. The heads of each double row of cows would be at least 3ft. apart. Liquid filth can at once drain away into the yard, and be pumped thence direct on to the fields. There is an ice house, with a wooden roof covered with thick felt. The dairy is under the living house. Butter and cheese are made. No cooling apparatus has been set up as all milk is made into butter and cheese. The water supply is from a well in a meadow close at hand, whence it is piped to the house and farm buildings.

We visited during our stay a variety of cowhouses, both great and small, and the general conclusion at which we arrived was that the Danes possess a somewhat higher estimate of the value of cleanliness in the cowhouse than, according to our experience, is possessed in this country. Still, we wish to state plainly that we saw nothing in this particular alone which is not frequently attained to in England, and which, by the exercise of more care and intelligence, could not be reached in many more instances—in a word it was not the superiority of the Danish cowhouses which impressed itself upon us so much as the intelligent manner in which the Danes make use of the often humble facilities at their disposal.

#### STATE CONTROL.

The Police Master of Copenhagen may direct his colleague in any locality from which milk suspected of having caused disease, may have come to examine the cows and premises, and to endeavour to trace the source of origin of the outbreak. If there be illness among the cows, the milk must not be sold, and if infectious sickness be discovered in the families of those associated with the dairying, proper steps must be taken to ensure freedom from all danger of the further transmission of infection.

Professor Storch and his staff at the Government Laboratory deal with 15,000 to 16,000 samples of food every year, including skimmed milk, butter milk, butter, and a few samples of whole milk.

The bacterial cultures for us as butter starters which are made in the State Laboratory approach as nearly as practicable to "pure cultures." The vast majority of Danish butter is made by the aid of such cultures.

Salt is the only preservative which is allowed to be used for dairying produce or margarine.

Professor Schou is of opinion that no need exists for the use of chemical preservatives other than salt in butter, or salt and saltpetre in bacon.

## Appendix.

The use of colouring in milk is forbidden, but is allowed in butter and cheese. The colouring of margarine is specially regulated, to admit of its ready detection, its conformation and labelling, as already stated, being also regulated with a like object. The use of arsenical colours or aniline colours prepared with arsenic is prohibited.\*

In Copenhagen most milk is still sold by small vendors. Some two-fifths of the population are believed to be supplied by large companies, using special measures of cooling and cleanliness, pasteurisation or sterilisation; that is, some 160,000 of the 400,000 people in the city are thus supplied. Much milk is boiled in the houses. It is a cheap commodity in Denmark, being only 15 or 16 ore (2d. per litre (about 1½ pint).

The attitude of the State in respect of the dairying industry may perhaps be regarded as consisting more in the encouragement of the industry than in its control by legal enactments, and an illustration of this attitude will be found in the section dealing with the control of tuberculosis in cattle.

This same spirit of helpfulness is apparent in the transactions of the "Dairyman's Association," to the expenses connected with which the State makes a substantial annual contribution. This association, which consists of a large number of the largest Danish creameries, encourages the growth of knowledge with regard to dairying by holding exhibitions of butter in Copenhagen at frequent intervals. The butter-makers in the country generally, some at one time, some at another, are suddenly apprised of the fact that an exhibition is about to be held, and they are invited to despatch forthwith a cask of butter, together with sundry detailed information with regard to its manufacture, such as the amount of salt used, whether or not the cream was pasteurised, and how far use may have been made of pure cultures. The suddenness of the appeal has the object of preventing special butters being made for the occasion. The butters are received into a cold room, and at the end of two days are examined by experts selected by the association. The casks are so arranged as to furnish no clue as to the owner of the butter or as to its source, a number alone distinguishing one sample of butter from another. At the end of the trial the numbers attached to the butter, together with the marks given, are published, each owner being thus informed of the opinion come to as regards his own butter alone. The information obtained at these butter trials is recorded by the association, and put to such uses as seem expedient for the promotion of the industry.

## CATTLE.

The milch cattle are mostly of the red Danish breed, but in Jutland the Jutland breed is well represented. They are tethered in the fields by chains of some 12ft. long, with a 3ft. iron staple to fasten in the ground by means of a mallet. They seldom drag their tethers, save under circumstances of great fear, e.g., at times of heavy thunderstorms or after very excessive rain. The cows are moved seven times a day, gradually from one side of the field to another. At Sofiendal Farm (see later) five men attend to the tethering of the 300 cows.

## TUBERCULOSIS IN CATTLE.

Denmark has by her law of March 1898 aimed at the extinction of tuberculosis in cattle by forbidding what was deemed to be a fruitful source of infection, namely, the feeding of calves by raw skimmed milk. That law enacts that all milk used for the food of cattle must be pasteurised, i.e., subjected, though it be but for a moment, to 85deg. C. (185deg. F.), such an exposure being apparently regarded as sufficient to kill the bacillus of tubercle. If by chance the pasteurising plant belonging to a vendor of skimmed milk be broken down, then the purchaser of the milk shall be informed, and the milk must be used for some purpose other than cattle food. This law does not cater (at least primarily) for the health of the human subject.

It is also not permitted to import from abroad milk or butter-milk which has not been heated to at least 85deg. C.

Numerous samples of milk are examined from time to time with the view to ascertain how far all milk intended for the food of cattle has been pasteurised in accordance with the statute above referred to.

\* Copper in peas is absolutely prohibited. The Danes eat tinned peas "off colour."

The test is very simple in its application, two small bottles and a test tube being alone necessary.

The reagents employed are para-phenylene-diamine and hydrogen peroxide. If the milk in question has not been heated up to above 80deg. C., a blue colour results; if it has been thus heated, the milk retains its normal colour. This blue colour is apparently due to an enzyme which is killed at 80deg. C.

As has already been observed, the "separator-residue" which collects on the inside of the separators has, by the Danish law, to be burned.

Of the two millions of cows in Denmark, only a small proportion have been tested for tuberculosis. Hr. Boysen, the Director of Slaughtering at Hamburg, estimated the number at 70,000. A farmer is under no legal obligation to have his cows tested, neither is he compelled to employ a veterinary surgeon for any purpose whatsoever. If, however, he elect to employ the test the State affords him certain facilities for so doing, the Government voting an annual sum of 100,000kr. (£5,500) for the purpose. All cows declared to have tuberculous udders must be killed in the public slaughter-house under the supervision of the police master, and the owner obtains compensation in the shape of one-fourth of the value of the cow, plus one-half the value of the diseased meat, together with such portion, if any, of the carcase as is certified to be fit for food. Compensation is granted only in respect of tuberculous cattle killed in the public slaughter houses. Cows having tuberculosis of the lungs need not be slaughtered by the State. If a private veterinary surgeon regard a cow as tuberculous he can settle any doubt he may have by taking or sending material therefrom to the State Veterinary Surgeon for examination. An owner suspecting a cow to be tuberculous is required to notify the fact to the State. He must not allow such an animal to be sent to market, or to be exhibited, or exported, and must not sell its carcase until the veterinary surgeon has declared it free from the disease. The milk of cows with tuberculous udders must not be sold.

## RAILWAY TRANSPORT.

Nearly all the railways in Denmark are State-owned. We had an interview with the officials in the General Manager's Department, and with the Traffic Superintendent at Copenhagen, who afforded us the following information:—

The railway companies aim at the transport of milk and butter by passenger train, but they are not, it is alleged, aided much in their endeavours by farmers or milk companies. For example, all orders reaching the railway authorities for carriage of goods on white paper forms are by the regulations to be dealt with on goods trains, and milk dealers with rare exceptions make use only of these white forms. Nevertheless the milk is delivered as quickly as possible, and is, moreover, wherever practicable, sent by ordinary passenger train without extra charge; just as is the case with goods notified on pink paper forms, but which are charged an added 50 per cent. of freightage. There is also a brown paper order form for goods of a very perishable character and needing immediate delivery, which ensures carriage by express train at added cost. There are privately owned ice wagons, e.g., Mr. Busck's vans, and some 120 ice wagons in the country in all. Ice costs the railway authorities 6kr. (6s. 9d.) per 500 kilogrammes; and each ice-furnished wagon costs the user 12kr. (13s. 6d.) in addition to freightage; charges which apparently go far to prevent general use being made of such wagons. But all butter and bacon for England are carried in this class of truck, with its double walls and roofs, the inter-spaces being filled with dried rice husks.

The wagons in which milk is usually conveyed are painted white, and while they have neither double walls nor roofs, and do not contain ice, they are specially ventilated by four ventilators, with upward draught, near the roof, two on each side of the vehicle.

Trains are arranged to run at hours convenient for the milk trade: e.g., a train leaves Masnedo at 5.40 a.m. and at 5.53 p.m., and passing through a dairying country, reaches Copenhagen at 9 a.m. and at 10 p.m.

Up to the time of our visit no milk had been exported from Sweden to Denmark, but two ferries are running from Copenhagen to Malmö, and each is capable of carrying 16 loaded railway wagons, and covering the 20 miles in but little over an hour.

The ice wagons are the invention of Professor Schou, who has, he told us, also invented an improved method

-of truck ventilation, whereby, with the addition to freightage of 2kr. (2s. 3d.) per wagon on ice, the value of meat transported to Berlin during the hot weather has been increased 380kr. (£21 7s. 6d.) per wagon over that sent in ordinary fashion.

#### OCEAN TRANSPORT OF BUTTER.

The export trade in butter from Denmark is an enormous one, and Mr. Harald Faber has marked for us a map of the country showing the chief ports for purposes of shipping butter to be Copenhagen and Naksör in Zealand, Svendborg in Funen, and Esbjerg, Frederikskøbe, Aalborg, Randers, and Aarhus in Jutland.

From Copenhagen all the boats leave on one and the same day each week, viz.: Thursday, for England via Hull and Newcastle-on-Tyne, and for Scotland via Leith. The reason for this simultaneous sailing we could not learn. Captain Parker of the S.S. "Rona," of Leith, kindly showed us over his vessel, the first to be fitted with a refrigerating apparatus, at a cost of £1,500. The chief engineer explained to us the machinery and its method of working. There are five holds, each of which can be kept at a temperature of 45° F. if necessary, but as a matter of fact, some 2,000 to 4,000 casks only form the weekly butter cargo of the "Rona." Each of these holds is piped under its deck covering, the cooling agent being brine of low freezing point, which is constantly circulating from the engine through the pipes and back to the engine again and again, to be cooled down before being sent on its way each time. The bulk-head and the double sides of the holds are lined with non-conducting material. Formerly the worst feature of the cooling apparatus was the dripping from the pipes of melted ice-water on to the butter casks in the holds, but this is now almost entirely obviated by bringing the machinery into action before the butter comes on board and by keeping it going until the butter has been removed again. Of course all such drippings were merely due to the condensation of moisture upon the cold iron pipes. Cloths are always spread on the casks to prevent any drippings that may still fall, from damaging the butter.

In company with Mr. Brienholt, the German Consul at Esbjerg, and one of the directors of the Danish Steamship Company, we visited the S.S. "N. J. Fjord," at Esbjerg, she being one of the company's vessels which is fitted with carbonic acid refrigerating plant for the purposes of the export butter trade, the arrangements being such as to enable any one of the holds to be cooled independently of the others. The refrigerating apparatus is started some hours before the vessel's departure in order that the temperature of the holds may be properly reduced in time to receive the cargo. Any of the vessels of this company can load from a covered quay, which protects the cargo from sun and rain, and it is intended to extend the roofing-in of the quay so as to permit of the cargo of three boats being loaded at the same time under cover. There are some two miles of piping on board the boat, wherein the brine (a solution of calcium chloride) is kept at not less than 4 deg. below freezing point, it losing about 3 deg. in its passage through the pipes back to the engine, which it leaves again at 7 deg. below zero. The double walls are lined with felt. The loss of space caused by the apparatus and linings is 5ins. all over the ship, and the extra weight is considerable.

#### A DANISH FARM.

##### SØFIENDAL, HASLEV.

Among the introductions given to us by Mr. Harald Faber was one to Hr. Ulrik, of Søfiendal, a large farm near the small town of Haslev, some 30 miles south-west from Copenhagen; and from this gentleman we received a cordial invitation to spend a day at the farm and see its various operations in relation with milk and butter. We were glad to be able to avail ourselves of the opportunity thus afforded us, and we accordingly devoted a whole day to the purpose, from the afternoon of one day to the evening of the next, returning by the train which brought with it much milk to Copenhagen from the southern parts of Zealand.

Søfiendal is a large farm of some 300 cows, and with a milk business of 50,000 to 60,000 kr. yearly, entailing an annual outlay on about 400,000lbs. of maize for cattle. It is managed by Hr. Ulrik for Count Moltke, who owns much property hereabout.

Milking is performed at 4 a.m. and 4 p.m. The tails of the cows are cut in winter for purposes of

cleanliness, and the coats of the cows brushed twice a day. Although it is not considered desirable to wash the cows' udders, each of the milkers has her own clean cloth wherewith to rub the udders in winter; and is provided once weekly with a clean blue apron to wear over her dress. Each milker washes her hands before beginning to milk, and rinses them between the milking of each cow. She milks from 18 to 20 cows, the milk being at once removed from the stable, emptied into a large can, and screened.

At our visit we saw the cows being milked in the fields. There was no cleaning of the udders then (it is not regarded as requisite in the open in summer), but the women frequently rinsed their hands, and the milk of each cow was at once passed through a fine metal gauze screen, which was covered with a white cloth, into a churn standing in a cart. The milk was also strained at the farm before passing over an 18-coil cooler, and it was then placed in an ice-water tank till despatched. The milk is weighed before being sent off, and the cans are sealed.

Very little morning milk goes to Copenhagen as whole milk, but as cream and half-skimmed milk.

The milk is sent by rail in ice wagons belonging to the railway company.

In future, the milk from Søfiendal was to be sent for butter and cheesemaking to "Triøfium" (see latter), instead of into Copenhagen.

We took the dimensions of one of the cow houses at Søfiendal. It serves for 112 cows, the heads of the cattle in each double row being 4ft. apart. The house is 45ft. wide, and each of its eight sections is 15ft. long and 12ft. high sufficing for 14 cows, and giving each of them 580 cubic feet of air space. There are seven doors in the stable, and 15 windows, all opening in part. The stable is quite in the open. Floor, ceiling, and walls are whitewashed twice yearly. Every two cows have one water trough, which automatically fills, but never overflows. This is regarded as a safeguard against tuberculosis, such as would not be procured by a water supply common to the whole herd. The water is from a pump well in the yard. The house is maintained as far as practicable at 13°C. (55°F.). The excretions, which are removed twice daily, fall into square-cut stone trenches in the rear of each row of cattle, which trenches form effective channels for the disposal of liquid filth. The cows are in the stables from October 1st to April 30th, never being out of doors during that time. 30lbs. weight of roots is given to each cow daily. Milk can be sent from cows fed as the farmer chooses so long as the butter derives no unpleasant taste therefrom.

#### KØBENHAVNS MÆLKEFORSYNING.

The Copenhagen Milk Supply Company, now for many years associated with the name of its originator, Mr. G. Busck, of that city, very kindly placed all their available information concerning methods of procedure at our disposal, and in the persons of the director (Forretningsfører J. G. Smith) and the analyst (Hr. G. v. Ellbrecht) we found capable exponents of the system adopted.

The business premises are situate at Frederiksberg, on the western side of the city, and they have in all entailed an outlay of about £15,000. There are employed some 170 adults and 160 boys, and 58 horses are in working. The company trade under a mark which consists of two heads of clover, one red and one white, on a black triangle, with a circular pink background. The water supply is from a well in the yard, taken from a depth of 51ft. from the surface. The water contains much iron, and is filtered before use.

The ice-house has double walls, with intervals of 2ft., the space being filled with sawdust, and beneath the floor there are arrangements for draining off the water resulting from the melted ice.

In August last, 35 farms were sending milk to the company. Every farmer's milk is tested, from 100 to 120 samples being chemically analysed, and some 40 samples physically examined, each day. Cows furnishing the milk must be kept in the fields till mid-September. The application of the tuberculin test is not now compulsory.

Much of the milk comes by rail in special ice-wagons belonging to the company. Ice is introduced by openings in the roof into ice receptacles situate at either end of the wagon, the receptacles being provided with waste pipes for the escape of melted

## Appendix.

ice. The ice is put in at the city premises, in order that the wagons may be sent back with the empty churns in a cool temperature. We found the air of one wagon to have a temperature of 14° C. (57° F.) on a hot August night, the wagons having finished a day's travelling to the farm stations. The temperature was 17° C. (63° F.) at 7 o'clock a.m. after the doors had been open all night. Each wagon takes 1,000lbs. of ice, and holds 105 milk cans each containing 50 litres. The ice comes from Danish lakes, and costs 2s. per 1,000lbs., including labour of housing it in the huge store chambers.\* The charging of a waggon costs about 2s. 6d. About five millions of lbs. of ice were used in 1889 on the premises.

Milk comes a distance of from 10 to 50 miles, the longest distance occupying three hours in actual transit. It leaves the country stations from 7 to 7.30 p.m., and reaches the premises in Copenhagen from 10 p.m. till midnight. Jyderup, Soro, Dregentved, Haslev, &c., furnish milk, and from the 1st September last milk was to come from Nykjöbing in Sweden, 7 hours' distance. The ice-wagons are attached to passenger trains. The milk is dispatched from farms so as to reach stations only half an hour before the departure of trains.

Milk is sent out for delivery in the city only once daily, so that although customers get their day's supply in two rounds, it is the same milk, the carts doing the circuit twice for the convenience of householders. No complaints have been received from customers. On Sundays, only one delivery is made. Forty carts start about 5 to 6 o'clock in the morning, each cart having its specified "round." At the houses of the customers the milk is emptied from the churns into small "cans," and from these into the domestic receptacles provided by the householders. The taps of the churns on the carts are covered by metal flaps to prevent the ingress of dust and dirt to the nozzles, and special milk in bottles is placed in ice in a separate covered part of the van. Superfluous milk left over after the days' distribution (some 5 per cent. as a rule) is put through a separator, and the resulting cream made into butter.

The farms furnishing milk have an average of 150 cows each. The conditions which regulate the feeding of milch cows, their milking, the delivery of milk, &c., are very strict, and have been in existence for many years. A translation by Mr. A. Stewart Macgregor, late British Vice-Consul at Copenhagen, runs as follows:—

## REGULATIONS FOR CONTRACTORS.

## A.—Feeding and Management.

I.—The food of the cows must be of such a nature and quality that no bad taste or taint may be imparted to the milk by it.

- a. Brewers' grain and all similar refuse from distilleries are strictly forbidden, as also is every kind of fodder which is not fresh and in good condition.
- b. Turnips, kohlrabies, and rutabaga are absolutely forbidden. No kind of turnip leaves may be used.
- c. Carrots and sugar beets (mangolds) are permitted up to half a bushel per cow, but only when at least 7lbs. corn, bran, and cake are given along with them. Cows supplying infant milk may get carrots, but never more than a quarter of a bushel per head.
- d. Oilcake. Rape seed cake is the only oilcake which may be used. 1½lbs. is the furthest limit, along with at least 5lbs. corn and bran. Infant milk cows must not receive any cake.
- e. The proportions in which the different kinds of food are to be given must be arranged with the company before the contractor commences to supply milk.

II.—Stall feeding in summer will not be permitted under any circumstances. The cows must be fed in the open air upon clover and grass. Vetches are forbidden.

\* Ice cost 16 kr. (17s. 10d.) per ton when imported from Sweden.

† Milk Supply of Copenhagen, by A. Stewart Macgregor 1899.

In a case of necessity dry food or cut corn may be given, but on the field.

III.—In autumn the cows must be clipped on the udder, tail, and hind quarters, before being taken in.

IV.—Calving should be so regulated that the milk sent in during the months of September and October is not less than two-thirds of the largest quantity sent in any other month.

V.—The milk of cows newly calved must be withheld for twelve days after calving, and must not be less in quantity than three imperial quarts per day.

## B.—Milking.

VI.—The greatest cleanliness must be observed during milking, and the milk must be strained through a wire sieve covered with a clean woollen cloth.

VII.—Immediately after milking, and during all seasons of the year, the milk must be cooled down with ice water to 40° Fahrenheit.

VIII.—Every contractor must be provided with a Lawrence cooler, which he can obtain on hire from the company.

IX.—Thirty pounds of ice, making due allowance for waste, must be kept in stock for every 100lbs. milk produced, which can be calculated from the fortnightly trial milkings.

## C.—Delivery of Milk.

X.—a. The milk must be delivered at the nearest station once or twice daily, according to the requirements of the company, either as whole milk, or as "half-skimmed" milk and cream.

b. The milk must not be sent from the farm earlier than is absolutely necessary for its arrival in proper time at the railway station.

c. In summer the van for conveying the milk to the station must be provided with a cover to protect the milk from the heat of the sun.

XI. The company will supply the cans necessary for transport.

XII.—The company cleanse the cans before returning them, but they must be carefully rinsed out with cold water as soon as they reach the farm again, to get rid of any dust or dirt which may have adhered to them during the return journey.

The cans must be placed in a cool airy spot, until again required, protected from all impurities, with lids off, and bottom upwards, but in such a position that the air can freely get into them.

XIII.—The cans may not be used for any purpose but the conveyance of milk.

## D.—Further Regulations.

XIV.—The contractor is bound, upon word of honour, to answer any inquiries made by the company concerning the milk supply.

XV.—The contractor must allow any of the veterinary surgeons of the company to inspect his cattle as often as the company requires, and must drive the surgeon to and from the station. The contractor is bound to follow out closely the instructions of the veterinary surgeon.

XVI.—Any cow declared by the veterinary officer to be suffering from tuberculosis must be instantly and entirely separated from the rest of the herd, and should be got rid of as soon as possible.

XVII.—The contractor must promise immediately to inform the company of any case of illness which may arise between two visits of the veterinary officer. If necessary, he must withhold his milk until the veterinary officer arrives and inquires into the circumstances.

In such a case the full price will be paid for the milk.

XVIII.—The contractor, to the best of his ability, must watch over the health of all who reside on his farm, or work upon it, also the families of the latter.

Should a case of infectious disease arise among any of them, he must immediately report the fact to the company, and withhold his milk, which will nevertheless be paid for as usual, if these conditions are fully complied with.

## Appendix.

I agree to the above.

Signature of the Contractor.

The following forms, Nos. 1 to 4, are regularly employed by the company :—

## Name of Farm \_\_\_\_\_

Number of Cows \_\_\_\_\_

Stock of Young Cattle —

(Signed) \_\_\_\_\_  
Veterinary Surgeon.

## Name of Farm \_\_\_\_\_

Contractor's Name \_\_\_\_\_

(Signed) \_\_\_\_\_  
Inspector.

(Signed) \_\_\_\_\_  
Inspecting Dairymaid.

## Appendix.

## 4. CIRCULAR.—INFECTIOUS DISEASES, COPENHAGEN MILK SUPPLY COMPANY, SOLBJERG, FREDERIKSBERG.

As the contractors are aware, it has now been clearly demonstrated by science that various infectious diseases may be transmitted through milk. It is therefore of the first importance to the company that no milk should be supplied to them from farms where there is any infectious disease in the families of the persons employed in milking. The company therefore earnestly request every contractor to report immediately any case of this kind.

The highest price in the market will be paid for the milk from such farms, as usual, if the notice is given in time to prevent it from being sold.

Requesting your signature to the enclosed, we remain,  
(Signed)

THE COMMITTEE OF MANAGEMENT.

Milk is placed in ice-water almost immediately after arrival on the premises. It is taken from the wagons as soon as they draw up at the special siding for unloading, the cans being raised to the level of the floor by a miniature lift. We saw the milk arriving on August 24th, another hot night, and found the air of one wagon registered 16° C. (61° F.). One milk can in the van was decidedly warmer than the others, the explanation was probably late milking and consequent omission to cool the milk at the farm. The temperatures of differing milks taken haphazard that night were 13°, 13°, 16°, 16° C., and one was 17° C. It would be about 6° C. when it left the farm, and all milk was again cooled down to that degree (43° F.). Women test the sweetness of the contents of each milk-churn, and throw aside the sample tasted; and it is stated that not even so rarely as once a month has milk to be rejected. Each churn's milk is also tested as to temperature, and a register kept. Each can bears a seal showing its source of origin. The milk remains standing in ice-water till morning, save that for children, which stands only half-an-hour for purposes of cooling.

Besides the cooling on reception by the company, milk has also to be cooled at the farms, the morning milk being kept in ice-water, and sent up with the evening milk, but in separate cans. The evening milk is sent whole, but, as a rule, only the cream of the morning milk.

Milk is screened at the farms as soon as practicable after being drawn. It is screened in the fields in summer, the milk of every two or three cows being put through a fine wire gauze covered with a cloth. Cows are milked in the sheds in winter, the milk being drawn away at once and screened.

The milk is efficiently filtered at the company's premises through four layers of gravel of varying sized pebbles and three layers of cloth. There is also a smaller filter with two layers of gravel and two of cloth to be used only for any small amount of milk urgently needed. The gravel is washed with hydrochloric acid, also with soda and water, and sterilised at 120°C. (248°F.) after each time of using. It is then dried in a high pressure steam oven. The process of filtration is upward, first through the lowest layer of coarse gravel, then through the intervening finer layers to the cloths of close texture. Before being filtered the milk that has been standing to cool is intimately mixed with a perforated crescent-shaped metal disc, and stirred to obviate any unequal distribution of cream.

The milk can be kept sweet in the hottest weather. No trouble has been felt in the 23 years during which the company have been working. Milk drawn one morning will not in ordinary course be all of it used till the evening of the next day; and this after having left the establishment about 6 o'clock on the morning of the day succeeding its being drawn, for delivery on two rounds to customers.

Milk for children comes from special farms, and is watered down for infants with water which has passed through a Pasteur-Chamberland filter, which is cleansed weekly. We tasted milk in the early morning which had been bottled over-night, which had a temperature of 10°C., and for which the current price was 20 ore (2½d.) per litre. All such milk is bottled, in ¼, ½, and 1 litre bottles. The filled bottles are kept in ice, both on the company's premises and in the covered carts.

The company purchase a good deal of cream from farmers who do not send milk, all such farmers being under contract. Milk for creaming must stand ten hours

at the farm. There are three classes of cream sold, namely—

|            |                                                                                         |
|------------|-----------------------------------------------------------------------------------------|
| 1st cream, | with 20 per cent. of fat, and costing 80 ore (10½d.) per litre.                         |
| 2nd " "    | 15 per cent. of fat, and costing 60 ore (8d.) per litre.                                |
| Extra " "  | 26 (ordinary) and 28 (summer) per cent. of fat, and costing 1 kr. (1s. 1½d.) per litre. |

Cream is sent long distances encased in wooden boxes with ice packed round the bottles, and an outlet for waste water. It is sent thus in 1-litre bottles, and also in cans holding from 3 to 10 litres each.

A large amount of the cream is sent to hospitals, and no complaints are made as to its condition. Indeed 2,000 Danish lbs. are annually sold without complaint. Cream in Copenhagen is vended only by dairymen and bakers; not by grocers. Some which had been whipped on the Saturday night preceding our visit was fairly "fresh" to the sense of taste on the following Monday morning. It should, however, be added, that the cream in question had been out during the whole of the hot Saturday "rounds" in the town.

Ordinary whole milk as received by the company furnishes 10-15 per cent. of cream, and has 5 per cent. of fat in summer, and an average at all times of 3.5 per cent.

About 300 Danish lbs. of butter (some 328 English lbs.) are made daily by the company. Such butter, as already stated, is made from milk returned from the town rounds, the cream used having been skimmed from the milk in question. All butter made by the company is sold in Copenhagen. A fresh starter is prepared for the butter every day. The cream, which has been previously cooled to 10° C. (50° F.), is some 34 hours old when placed in the churn. The act of churning usually occupies about half-an-hour. Danish salt to the amount of 3 per cent. is added by hand on the butter-working table, after the butter-milk has been expressed. This quantity of salt suits the local taste. No pasteurising is attempted, and no advantage is held to accrue from the use of pure cultures. It is thought that about 12-14 per cent. of water remains in the finished butter. The price of butter at the time of our visit was 1 kr. 20 ore per Danish lb., about 1s. 4d. for 17½ ozs. English.

Butter-milk is sold in the town, and is used by all classes. Some hundreds of pounds are sent once a week to England for use in the manufacture of biscuits, a quantity being several days old when despatched.

Great attention is paid to the cleansing of milk and butter receptacles by the company. The workers throughout the establishment are all in white, and are supplied with clean covering aprons twice weekly. The cans are cleaned by brushing with hot water and soda, and later washing out with hot water and lime, a ladleful of soda, about ½ lb., being used for each pail of water, and 20 lbs. of lime to 900 litres of water. The outside is then washed and steam injected into the cans, which are left to drain alike by the company's servants and by the farmers. The latter have not their own cans. The apparatus in which the cans are washed is itself subjected to like cleansing. Bottles are first washed in soda and water, then placed over revolving brushes, and then steam-sprayed. The corks, which are used only once, are of special make, and are tied by hand and sealed. The butter pots and lids are washed in soda and water, and the pots only in lime and water also.

## DET DANSKE MÆLKE-COMPAGNI.

## SYSTEM CASSE.

We had the pleasure of being taken over the premises of this company by Director Fr. Salicath, this establishment also being situated at Frederiksberg. It has been working for three years, and is a wholesale business house only. It trades under the mark of a polar bear on an ice floe, with sun rising over the hill behind a strip of open sea.

The premises, which are paved with close-fitting stones in all parts, presented at the time of our visit a very cleanly appearance. The water is softened prior to use, and is obtained from a well sunk 170ft. into the chalk.

The business is a large one, some 35,000 litres of milk and cream coming daily from farms having from two to as many as 300 cows each. Milk is tested every day, sam-

ples being sent to the laboratory. The greatest distance from which milk and cream comes is 150 kilometres. The milk, which arrives in cans holding 50 kilogrammes each, is weighed on arrival, then placed in tubs, and pumped into a reservoir.

Milk in excess of the immediate demands is frozen and stored; it is used in a manner subsequently to be referred to.

Farms furnishing milk and cream are under the usual regulations, and subject to the visits of the inspectors and the veterinary surgeons connected with the establishment; these latter make monthly visits. Cows are tested and examined, and tuberculous cows are at once got rid of. The milk of newly-calved cows must not be supplied, and that from farms in which infectious disease exists is paid for but not used. Milkers must clean the cows' udders before milking, and must wash their hands immediately prior to the process. The farms must have ice for purposes of cooling milk.

Milk must not reach the establishment at a temperature above 10° C. (50° F.). The usual temperature on arrival is 15° C. (59° F.) in hot weather, but milk is often refused on account of its excessive temperature. Morning milk is sent in with the evening milk, but in separate cans. The special wagons which are used on the railways by this firm carry no ice, but are provided with double walls, and straw is laid on the top of and between the milk cans. The cans containing the milk to be cooled on the premises are placed in cooling tanks filled with ice, netting being spread over the cooling tanks to prevent birds from approaching too near to the milk, which is kept in the ice for some 2-3 hours from about midnight. Milk is 4-5° C. (39-41° F.) when bottled; and a small piece of ice is placed over each bottle in hot weather to keep the milk sweet and cool until sent out in the morning.

Farmers strain but do not filter the milk, which is centrifugalised on the company's premises, and passed through a filter of large sized pebbles, by an upward flow, just prior to being bottled. The filtering material is thrown away after each time of using.

All whole-milk sent out in bottles is pasteurised, the preparation for pasteurisation being as follows: Huge vats, each capable of holding 500 litres, are partly filled with milk, and to each 300 litres of this milk there is added 200 litres of milk in a frozen state. The mixture of solid and liquid milk is then kept in the vats for an hour and a half, until the whole is fluid. The milk is then pasteurised by raising it to 85° C. (185° F.), keeping it at that heat for two or three minutes, and then passing it in the usual manner over cold water coils. Metal lines are laid in the company's premises for facilitating the removal of the large vats from place to place; and trollies for holding four of the 50 kilometre cans are able to be wheeled about by one man. There is standing room for 30,000 litres of frozen milk in the refrigerating shed, in case it should be necessary to store such a quantity at any one time.

All skimmed milk delivered from the dairy is pasteurised. It is sold in 50-litre cans.

Milk is bottled automatically by means of self-acting siphons. Papier-maché "corks," made on the premises, are used; they are boiled in paraffin, but there is no resulting smell, the corks being dried under extreme heat. Bottles to be cleansed are first fitted upon a revolving wheel, and by this means are carried through a bath of soda and water; they are subsequently washed out with revolving brushes, and finally sprayed with cold water.

Bottled milk will keep for one day in the hottest weather, and for two days in cool weather.

Some 2,000 litres of cream are sent out daily, in three classes:

|                                          |           |
|------------------------------------------|-----------|
| 1st, 30 per cent of fat, 1kr. (1s. 1½d.) | per litre |
| 2nd, 15½ " " 45ore (5½d.)                | "         |
| 3rd, 14 " " 40ore (5d.)                  | "         |

the latter going largely to bakers.

An experiment, that failed to pay, was made of sending pasteurised milk in bulk to England, Scotland, and Buda-Pesth. The milk was sent in a frozen condition in a large can or receptacle surrounded with thick felt. The English importers refused to pay 14 ore (1½d.) per litre for milk, and would not pay 1kr. (1s. 1½d.) per litre for cream containing 42 per cent. of fat, while

Copenhagen was paying that price for 32 per cent. of fat.

The company make butter only to the extent of some 30 to 40lbs. daily in summer, but 300 to 400lbs. each day in winter.

#### THE MILK SUPPLY PASTEUR.

This firm, which has been in operation for five years, and which deals in the main with bottled milk, was devised and projected by Director Krohne, with the scientific co-operation of Professor Faber and Dr. Schierbeck of Copenhagen. The staff is a large one, 300 workers, including boys, being employed, and 80 horses being necessary. There is an ice-making plant on the premises. About 40,000 bottles of milk are pasteurised daily.

The farmers supplying the milk are under detailed control, and every month or three weeks the farms are visited by a veterinary surgeon attached to the establishment. There are fixed regulations as to the fodder of the cows, for the treatment of the milk, and for the notification of tuberculosis.

The institution itself is situated in the outskirts of Copenhagen and the railway waggon which convey the milk to Copenhagen are not provided with ice chambers. The milk on reaching the factory is received into a reservoir when it is duly weighed and strained, and from this it is pumped to a filter consisting of layers of gravel and felt, the whole apparatus being carefully sterilised daily.

After filtration the milk passes to the cooling apparatus, and from this to a second reservoir, from which it is pumped to the pasteurising apparatus (which is also sterilised daily after use) where it is raised to a temperature of 85° C., the whole process being so arranged as to exclude the admission of air-borne organisms. The milk is then cooled to about 5° C., the pasteurising and cooling occupying altogether about 5 minutes. From the cooler the milk is led to a reservoir, also guarded against the entry of extraneous organisms, and from there to the bottle-feeding apparatus, a machine fitted with tubes, by means of which the bottles can be conveniently filled.

The bottles, which are furnished with glass stoppers, are, after being filled, carefully sealed to prevent their being tampered with.

The employees who are brought in contact with the milk are all under medical supervision. In the event of their being ill they are refused admission to the factory, and the same exclusion obtains if infectious disease is present in their homes. They receive under such circumstances full pay during their absence.

The bottles which are used for small quantities of milk, as also the cans which are used for large institutions, are first thoroughly cleansed in hot water to which soda has been added—the interior of the bottles being washed out by means of revolving brushes—and after this they are completely sterilised in a large steam disinfecter which is kept at a temperature of 105° C. for half an hour.

The several processes are under daily control, both chemically and bacteriologically. Specimens of pasteurised milk are tested daily by Professor Storch's reaction to ascertain whether or not pasteurisation has been properly accomplished. Bacteriological examinations are made daily, and the percentage of fat is also estimated.

#### THE ADVANTAGES CLAIMED BY THE SYSTEM.

Dr. Schierbeck was good enough to set out for us the advantages claimed by the process, and they may be thus summarised:—

1. All danger from the possibility of infection of the milk, either at the farms or during transit is thereby discounted.

2. The distribution of the milk in sealed bottles is a safeguard against its infection or contamination in the milkshops or in the streets.

3. The milk awaiting consumption in the houses is kept free from contamination by means of flies, dust, or polluted air.

It is claimed that this is the only practicable bottle system for milk at moderate price, and that the pasteurisation of the milk places less onus on the farmers as to cooling, etc.

Appendix. It is, moreover, urged that the conveniences which are afforded by bottled milk are likely, in at least some degree, to present a remedy or alternative for some of the spirit drinking proclivities of certain sections of the community.

It may be added that, as regards children, the Copenhagen Health Department advise sterilised milk in preference to pasteurised milk. The boiling of milk for infants is common in Copenhagen, many people using Sohlet's apparatus, which costs about 11s., for the purpose.

#### HASLEV CO-OPERATIVE DAIRY.

As being typical of an industry which is in operation to-day in different parts of rural Denmark, we visited, while at Sofendal, the small dairy at Haslev town. It is a self-contained creamery on the co-operative system, and complete down to its telephone and its own electric plant. The water supply is from a well sunk 62 ft. into the chalk. No ice is used, cooling being effected by cold water only. The engine is of 6 horse-power, and the boiler of 14 horse-power.

The milk from 1,200 cows is dealt with daily. All the milk on receipt passes through a strainer fixed over the weighing machine, and also through a centrifugaliser, each centrifugaliser dealing with 3,600lbs. of milk per hour. Milk is then warmed to 40°C. (104°F.), the cream and the skimmed milk running by separate channels to different pasteurising plant, each being pasteurised at 90°C. (194°F.), the cream thereafter being cooled down to 10-12°C. (50-54°F.) by means of a cold water coil-cooler. The pasteurised skimmed milk is returned to the farmers, each of whom has his own cans. The cream is again heated to 40°C. (104°F.), and the butter started from Copenhagen Laboratory introduced. The cream stands till next morning, when it is churned for half an hour, the colouring matter, 5lbs. per cent. of butter, being added in the churn. Each churn makes 180-200lbs. of butter in half-an-hour. When the butter-milk has been expressed, on the worker, salt is added in the proportion of 7 per cent. for Northern England, and 2 per cent. for London. The salt is thought to lose three-sevenths of its weight in the working, at least 40 revolutions of the table being made. The butter is placed in cold water after being worked, and is again put on the table before being packed in casks, the retention of not more than 11 per cent. of water in the finished article being aimed at, and not more than 16 per cent. permitted.

Here, then, was a small co-operative dairy in full working, 30 miles from any large town, replete with all modern appliances, and self-contained in all essentials.

#### THE CO-OPERATIVE DAIRIES OF THE ISLAND OF FANÖ.

As instances of the ability of the Danes to work on the co-operative system in a small way, we may refer to the creameries situated on the Island of Fanö off the western coast of Denmark, near to the town of Esbjerg. At either end of this island is a small town or hamlet, and a complete co-operative creamery at each place draws its milk from the neighbouring portion of the island. The larger of these two creameries is that situated at Nordby, opposite Esbjerg, the smaller being at Sønderho, at the southern extremity of the island. Both creameries are practically identical, and a brief description of that at Nordby will suffice for our purpose.

The creamery draws its supplies from some 300 cows kept in that part of the island, each farmer possessing from three to five cows. The whole-milk is delivered on a platform outside the creamery. It is there weighed, warmed, centrifugalised, and pasteurised in the usual fashion, the resulting cream being cooled and prepared for churning, the separated milk, which has, of course, also been pasteurised, being returned to the farmers or otherwise disposed of.

The butter, which is lightly salted, is for the most part for purely local consumption. The milk churns are not cleaned at the creamery, but by the farmers themselves; the water supply to the farms is usually from shallow wells.

All the machinery, including furnace, boiler, heater, separator, and pasteuriser, is quite complete, both at

Nordby and Sønderho. Ice, save quite in the hottest weather, is not found necessary.

#### "TRIFOLIUM," HASLEV.

A large co-operative society had quite recently been established at Haslev, under the name of "Trifolium." The buildings were nearly completed at the date of our visit, and we had the good fortune to be taken over by Hr. Ulrik, to whom the accomplishment of this great movement is primarily due. The buildings are spacious, well paved, ventilated, and lighted, and replete with modern fittings, plant, appliances, etc. The company will have their own electric plant. The water is obtained from a deep well in the quadrangle. There are two boilers, one of 25 and one of 50 H.P. Milk will be sent by 41 farmers, owning 6,000 cows, the milk churns on arrival being emptied automatically, and then passed by an automatic gear to the cleaning room, where all cleansing operations will be performed by steam. The whole-milk will be at once weighed, and centrifugalised in Laval centrifugalisers; the cream will then be pasteurised, cooled to 15°C. (55°F.), and placed in cisterns, where it will stand. A starter prepared with a culture from the Copenhagen Laboratory will then be added in the cream, which, when ready, will be churned. Each of the six churns will make 150lbs. of butter in half an hour, 900lbs. in the aggregate. The butter-milk will next be expressed, and the salt mixed in by machinery. Long tables, probably with marble tops, will be used for making up the butter into English pounds. A pump will raise the butter-milk to a pasteuriser, from which it will run to a cistern. Some will go to farmers, and some to the cheese-making section.

In addition to the butter made on the premises, the company will purchase supplies from small farmers and from 41 smaller co-operative societies. Each of the smaller societies will form a central creamery to which cowkeepers will send their milk, owners of from 1-30 cows thus disposing of their milk in butter making.

It is estimated that, in addition to the butter made from milk of 6,000 cows, sent direct every day to "Trifolium," there will be received daily cream from the produce of 3,000 cows by rail, and each week some 30,000lbs. of butter from the 41 subsidiary societies above referred to.

The butter received and made on the premises will stand for twelve hours in the cold chambers which are to be cooled by means of the usual ammonia apparatus, the cooled air entering at the top of the chamber, being allowed to descend by virtue of its superior weight on to the butter. The butter will then be packed in lb. rolls and put into casks. The cooling chambers which are provided with double walls and doors, the intervals of which are filled with dried rice husks, can be kept at 3°C. (37°F.).

Skimmed milk will pass to another section of the building and be subsequently used for cheese-making. There is storage room on the premises for some 300,000lbs. of cheese. The store-room walls are double, and lined with non-conducting material. The room can be warmed or cooled at will, and the amount of moisture contained in the air can also be regulated; by these means the results of climatic changes can be in large part obviated.

Ice will be made on the premises, and also the wooden casks and boxes for butter, etc.

#### ESBJERG CO-OPERATIVE BUTTER FACTORY.

The director of this important factory was good enough to allow us to inspect it, and to afford us the following information relative to its operations.

The factory is supplied mainly from the neighbourhood of Kolding, but also from other places in the northern portion of Jutland. The butter arrives by rail, either in white-painted or refrigerating vans, according to the exigencies of the situation.

Although this establishment is only five years old, it has the largest business of its kind in Denmark, and employs about 150 hands. It exports no less than ten million lbs. of butter every year (27,500lbs. daily), none of which is made on the premises. All butter reaches the factory in a half-worked condition from some sixty large creameries. These creameries send (1) fresh butter, saltless on arrival, and (2) butter containing some 3 per cent. of salt. Some of the saltless butter is sent, still saltless,

to England, as also is some to which only one per cent. has been added, so that it will contain only about one-half per cent. on leaving the establishment. It is the only known factory in the country which packs absolutely fresh butter, and in connection with the keeping powers of this butter it may be here recorded that it has been despatched to the Paris market *via* Esbjerg, Harwich, London, Southampton, and Havre. Such butter, in spite of delay, etc., on the English railway, has reached Paris quite fresh and has fetched 4½ francs per kilo. But whether the butter be salted or fresh, it will keep upwards of three weeks, if only it be quite fresh and sound when it reaches the factory from the creamery. (Otherwise it tends to "go off" more rapidly.)

The butter on its arrival at the factory is classified, and the different supplies of each class are blended. Any not regarded as good enough for packing in rolls is salted, and sent away as second-class butter, but this very rarely happens, as a very low price is paid to creameries for such an article, and, in addition to the consequent endeavour of the suppliers to furnish butter of first-class quality, there is the fact that all dairies desirous of joining the society must have acquired a high character for produce on three successive occasions at local exhibitions. It goes almost without saying that all cream used for the butter has been pasteurised, the exigencies of the English market being said to render this process essential.

After its receipt and blending, the half-worked butter undergoes its first working at the factory, the salt being added at the time of its second working there. It is worked a third time for purposes of ensuring the expression of as much butter-milk as possible, and herein it is thought lies the excellence of its keeping quality. Butter for the London market is coloured with Danish colouring matter.

Each pound is separately weighed by women or girls, who frequently rinse their hands in hot water, and it is then wrapped in parchment and enclosed in a cartridge paper box. The butter is despatched to England in five boats weekly, three steaming to Parkeston Quay, Harwich, and two to Great Grimsby, some of the vessels carrying refrigerating plant. The butter is some of it only four days from the churn when the English retailer gets it on his counter, and is none of it more than five or six days old. If it have to travel far from the creamery to the factory, ice waggons are used; but if not, then white-painted and well-ventilated vans.

The manager informed us that when the butter reaches England its troubles as to keeping begin. If white-painted or iced vans were used on the English railways here concerned, the Danish butter merchants would much appreciate it.

There are cold chambers at the factory, which are kept at 2°C. (36°F.). They have double doors of a specially designed form to effectually exclude the warm outer air. The ammonia cooling apparatus is used for keeping the chambers cool, and the factory also generates its own electric lighting. No ice is employed or deemed necessary, though the creameries use ice if they have no cold chamber.

Butter tubs, which are of oak, are made on the premises, as also are the boxes, which are constructed of pine wood from Norway. The tubs are cleansed by immersion in large cisterns filled with chalk and boiling water, chalk being regarded as a good cleanser.

The water supply of Esbjerg is from a deep well two miles out of the town.

### CONCLUSION.

Although, as we have already stated, we propose to allow this report to tell its own story, a few comments may perhaps be made with the view of focussing the information collected. As regards Amsterdam and Hamburg it is apparent that in respect of the former the use of pasteurised or sterilised milk is rapidly increasing, and in respect of the latter that the addition of preservatives to milk is, as the result of a recent Act, becoming rare. There would seem, so far as we were able to ascertain, no serious obstacle in the way of supplying either Amsterdam or Hamburg with milk free from preservatives.

Our attention, however, has been mainly directed to Denmark, and it is to the practice there current that the remainder of our remarks will have reference.

It is clear that the Danes have appreciated in theory and have recognised largely in practice the vast importance of cleanliness, straining and cooling in dairy

operations. These principles have permeated to the rural districts of the country, and by even a partial observance of them the Danes have been able to comply with the provisions of the law which prohibits the use in milk, cream, and butter of "preservatives" other than salt. Moreover, they have in certain instances dispensed with even small quantities of this latter article, and exported absolutely saltless butter to this country.

The Danes as a nation have recognised in a manner, and to an extent which is at present foreign to this country, that the destruction, inhibition, or regulation of bacterial activity is the basis of all successful dairying operations. They have appreciated in a practical fashion the fact that, in so far as milk is concerned, bacteria, some of which are associated directly or indirectly with the decomposition of such milk, may gain access to it from the time at which it leaves the udder of the cow to the time at which it reaches the consumer's mouth. Consequently they have set themselves the task of prohibiting as far as practicable the access to milk of all harmful bacteria, and of inhibiting the growth of such as may have gained access thereto.

This they have endeavoured to bring about by, among other precautions, encouraging the cleansing of the cow's udder prior to milking, by instructing the milkers to cleanse their hands, and by providing them with clean overalls.

Moreover, the Danes are alive to the importance of well-ventilated and well-lighted cowsheds furnished with floors and walls of an impermeable nature, and to the expediency of the frequent removal of manure from such cowsheds, although these principles have, as yet, only received partial recognition in actual practice. As we have already observed on page 283, we were not in our inspections so much impressed with the general superiority of the Danish cowsheds, as with the ability of the Danes to take full advantage of the somewhat meagre accommodation which is at times at their disposal. The Danes have a better grasp of the principles governing the keeping powers of milk than have the people of this country.

In the treatment of the milk after milking they attach due regard to its immediate removal from the relatively close and likely-to-be-contaminated air of the cowsheds, and to the necessity for this removal to be followed by careful straining and the best available means of cooling.

The Danes recognise the value of immediate exclusion, by fine straining, of such hairs and other materials as are likely to be coated with bacteria, and of the advantages to be gained by inhibiting the growth of bacteria by cooling. References may be made to the careful filtering through gravel and felt which takes place at certain institutions, and of the cleansing properties of the separating process.

In so far as the dairy utensils are concerned the absolute necessity of most scrupulous cleanliness, or of actual sterilisation by steam, is laid particular stress upon, and in respect of transport the use of refrigerating vans and of steamships fitted with refrigerating apparatus is daily increasing. Precautions are also taken to reduce to a minimum the duration of exposure of milk churns at railway stations by retaining the churns under cool conditions until their despatch to the train is called for. In places where the pasteurisation of milk is in vogue the immediate cooling of such milk after pasteurisation is regarded as an essential part of such process, the subsequent cooling being held to take from the milk any "cooked" flavour which it might otherwise retain.

It will have already been gathered that, as a matter of fact, the population of Copenhagen (some 400,000) are supplied with milk and cream without the aid of preservatives.

With regard to Danish butter it may perhaps be useful to relate that of the foreign butter annually imported into this country more than half is of Danish origin, and that such butter contains no preservatives other than a small quantity of common salt. Even this is in some cases omitted.

The departure taken by the Danes in the manufacture of butter has afforded an object for the study, and in some cases for the emulation, of other European nations.

Year by year the manufacture of butter from pasteurised cream prepared for the churn by the use of pure cultures has been practised in an ever increasing degree.

## Appendix.

In connection with the subject of pasteurisation it is, we think, of importance to point out that cleanliness is regarded as a very necessary precedent to the process. If once the bacterial products have conferred upon the milk or cream any unsatisfactory flavour we are assured by Danish experts that no process of pasteurisation can remove such flavour.

By such pasteurisation the Danes have aimed at destroying what may be termed the *unknown* in the bacterial flora of cream, in order that by the use of "pure cultures" of bacteria they may be able to substitute the *known*. Their position is that without such precautions the production of a butter having a characteristic aroma is more or less a matter of chance, and hence cannot be absolutely relied upon. The essence of the usual method of butter making is to endeavour to bring about conditions which are favourable to the development of certain species of bacteria; the essence of the Danish method is to kill or inhibit the growth of all the bacteria concerned in the process of "ripening" and to promote the necessary souring of such cream by the introduction of a starter prepared from "pure cultures." By this means butter is manufactured which can be safely exported to England without the use of preservatives. It is of interest in relation to the bacterial flora of cream to note that there would appear to be a

tendency to pasteurise at an increasingly high temperature, and experience indicates that, within certain limits, the higher the temperature at which the cream is pasteurised the better is the resulting butter likely to be. The progress of the practice of pasteurisation in Denmark has indeed been remarkable, and at the present time the vast bulk of Danish butter is made from cream thus treated. The passing of the law of March 26th, 1898, which renders the pasteurisation of milk used for the food of cattle compulsory, has doubtless been a force in the diffusion of the custom of cream pasteurisation, but the practice seems to have become general mainly owing to the satisfactory results which in the opinion and experience of the Danes have accrued therefrom. Moreover, the fact that the process is calculated to destroy most, if not all, the pathogenic bacteria has not been without its influence in a country where the care of the public health is made a matter of considerable concern.

It is, too, in our view, obvious, whatever opinions may be held as to the merits or demerits of the co-operative system, which has seen such a remarkable development within recent years in Denmark, that such system is very largely responsible for the numerous safeguards against the contamination of the milk, cream, and butter to which reference has now been made.

H. TIMBRELL BULSTRODE.  
CHAS. J. HUDDART

## APPENDIX No. IV.

REPORT ON A VISIT TO IRELAND IN RELATION TO THE USE OF CERTAIN PRESERVATIVES  
IN DAIRYING AND HOG PRODUCTS.

With the object of supplementing the information obtained during the visit paid by two of our number to Amsterdam, Hamburg, and Denmark, with special reference to the use, or otherwise, of certain preservatives in the dairying industry of these places (see Appendix No. III.), we in mid-September last proceeded to Ireland. We had here in view the investigation of the actual conditions under which butter is manufactured, our object being to ascertain from personal observation how far the use of preservatives is imperative in Irish butter, or how far, as certain witnesses had stated, the use of these substances could be dispensed with.

In addition we were enabled to learn something of the conditions under which Dublin receives its milk supply, and of the methods of using preservatives in the bacon and ham curing industry.

The following account of our visit consists essentially in a transcription of the shorthand notes which were taken down at the time of our inquiries, observations, and cross-examinations. We have elected to take this course rather than to compose an essay upon all the aspects of Irish dairying, in the writing of which the facts which are alone essential to our inquiry might perhaps have lost their proper values. Here and there we have drawn such inferences as seemed to us deducible, and, moreover, we have at times introduced matter which although not strictly within the terms of our reference, cannot fail, we think, to be regarded as pertinent to the subject under consideration. It may, too, be added that our inquiries in Ireland were concerned for the most part with the second portion of the reference to the Committee, i.e., to ascertain "to what extent and in what amount preservatives are used."

In all, we were three weeks in Ireland, of which time not a little was necessarily spent in travelling, and although we saw as much as possible of the great butter producing regions in the south and west of the country, we were only able to prosecute our enquiry to a very limited extent in the northern parts of the island. This we regretted, as we should have been glad to have ascertained for purposes of comparison with the south the practices now common in the north. In and around Dublin we spent three or four days, deriving much cordial assistance from the Government departments, and from the Corporation in the persons of Sir Thos. Pile, Bart., then Lord Mayor, and Sir Charles Cameron, the Principal Health Officer.

We had several conferences with Sir Charles Cameron, and for much of our knowledge as to the actual conditions affecting the milk and butter supplies of Dublin we are indebted to him and his medical colleagues, as also to Mr. Watson, the Chief Veterinary Inspector of the Corporation.

It may be at once stated that there is no legislation peculiar to Ireland on this subject, and that the only laws touching the question of deleterious additions to food in Ireland are the Sale of Food and Drugs Acts common to the British Isles.

*The Dairying Industry in and around Dublin.*

As regards Dublin, Sir Charles Cameron informs us that the city draws its milk chiefly from some 250 dairies within the city boundary, the source of the milk being almost entirely local. In his opinion the use of small quantities of preservatives in milk is preferable to the consumption of bad milk. Although no systematic examination of milk has so far been made with regard to the presence of preservatives, in Sir Charles's opinion the practice of preserving milk or butter is, in Dublin, relatively rare. By Sir Charles's kindness we were enabled to secure the views upon the subject of our inquiry of seven of the Metropolitan Health Officers. These gentlemen were good enough to meet us at the office of the Town Council. The following is a copy of the resolution which they handed to us on September 13th, 1900.

"That in the opinion of the Dublin Metropolitan Medical Officers of Health, the use of drugs in food preservation is most reprehensible, and should be discontinued; although very minute quantities might be used without detriment, yet the unskilled doctoring of food by active drugs is dangerous.

"(Signed) John Garland.  
Michael Strahan.  
Henry W. Oulton.  
J. P. Quinn.  
J. D. Crinion.  
G. A. Stritch.  
Henry G. Day."

In the course of conversation with these officers we learned that consumers in Dublin do not habitually add chemical preservatives to their milk, but one farmer at least is known to be sending preservative milk to Dublin.

The very poor often get their milk but once a day, and they frequently possess inferior, if not very bad, accommodation for its storage in their houses. But the majority of the poor are not accustomed to store such milk as they purchase for any length of time, and one or two of the officers told us that it is a common practice for the poor to buy their milk in extremely small quantities as often as needed.

Sir Charles Cameron regards the relatively high infantile mortality of Dublin as being largely due to the use of milk in a state of partial decomposition. He entirely agreed with the view of his colleagues in the Dublin Health Service as to the insanitary methods of milk storage in the homes of the poor, where also the cleansing of milk vessels receives too scant attention. Still, that there is no necessity for the use of preservatives in the city milk service, was the testimony of the health officers as the result of an intimate knowledge of the actual conditions of the trade in the city.

Suckling is general in Dublin. Hand or bottle feeding is very rare. The opinion was expressed that for every twenty children bottle-fed in England there is only one child so fed in Dublin.

At one dairy in the city which we visited, we found the shopkeeper with the preservative known as "Aromaticus" in his back premises, the full directions for its trade use being given in a book issued by the Agricultural Chemical Society, Southampton.

Mr. Anderson, Secretary of the Irish Agricultural Organisation Society, with whom we had a long conference, and to whom we shall have occasion further to refer, expressed his opinion that chemical preservatives are quite unnecessary in milk. On the general question of preservatives, he said that the matter was for him one of trade principles only, and not one of public health. His objection, for example, would be met if the labelling of preservative food and drink were made compulsory. He informed us that farmers sending milk to creameries for purposes of butter making do not use preservatives, but that those sending milk to a given town or institution as a rule use them largely. This he knows to be done in Dublin from the results of actual analyses. He thinks that preservatives militate against cleanliness in dairy farming. The cleanly farmer gets no better price for his produce than that obtained by the careless trader who covers his uncleanly methods by the use of preservatives.

The actual sterilisation of milk upon a large scale is not practised to any great extent in Dublin, but at Glasnevin, near to the city, a certain amount of milk is thus treated (see page 295). We obtained the views of the seven health officers already named, on the question of sterilised milk as an article of infants' diet. Drs. Garland and Quinn have no objection to offer to its use. Dr. Day advises actual boiling of the milk. Dr. Oulton is in favour of the boiling of milk, and Dr. Strahan is of opinion that it is better to boil milk than to stop short of boiling. Dr. Stritch has some objection to the use of boiled milk for infants. He prefers that the milk be pasteurised. He has witnessed bad results from the use of boiled milk. Dr. Crinion thinks that all milk should be sterilised. He has known many cases of diarrhoea to have been caused by sour milk, and has seen good results accrue in that disease from the use of sterilised milk. The boiling of milk is urged on householders by the Health Department of Dublin. It may, too, be mentioned that Dr. O'Dwyer, Health Officer of Tipperary, told us that in that part of Ireland but few mothers nurse their children. It is a common practice for mothers to boil the milk each morning, whilst the better class householders boil all milk coming into their homes.

In Dublin cows are stalled for 5-6 months each year, and in some few cases all the year round. The cow-houses are required to provide 500 cubic feet of air space per cow, and to be whitewashed in March and October. The Local Government Board for Ireland have issued model regulations for the use of local sanitary authorities desirous of regulating dairies, cowsheds, and milkshops in their districts, but we gathered that these have been adopted in a few instances only. There would seem at present to be very little control exercised as regards the sanitary condition of dairies and cowsheds in the country generally. It is in contemplation, Dr. Browne of the Local Government Board told us, to do something more in this direction.

At our request Mr. Watson kindly took us to see some Dublin cowsheds which, he stated, were

average types of such places in the city. One in South Dublin is registered for 24 cows. In the cowshed, which was very dirty, were 18 cows and 5 calves. The cattle and their udders were fairly clean, but as the cows were able to lie down in their stalls, opportunity was afforded them of fouling their udders. There was, however, a depression in the floor behind each for the droppings, and also a channel for carrying away liquid filth. The flooring of the sheds was good, but the open yard was cobbled, and on each side was an immense store of manure. The city water (Vartry) was laid on to a tap close to the sheds, which latter were, as is usual hereabouts, open on one side. Water was heated for the cleansing of milk vessels in a boiler in the kitchen behind the milkshop. No preservatives were, we were informed, used.

In another case in South Dublin we found the cows fairly clean, but the extremities of their tails were coated with filth. They had straw beds. There was a sloping surface behind the cattle, and the space on which they were standing was clean. But the surface on the other side of the shed was filthy with old manure, and here a horse was stalled. There was a central channel for the drainage of liquid filth, but the channel was rendered ineffective by stopping short of the drain connection outside the shed, and nuisance was thereby created. Mr. Watson had recently condemned the place on account of want of proper ventilation and sufficient air and cubic space, etc. The shed was open at either end, and contained about a dozen cows. There was a large accumulation of manure in the yard, draining to a trapped gulley, which was broken. The water supply was taken direct from a cistern which was used also for the flushing of the w.c. The owner said he always washed his hands before milking. The milk cans were generally washed in boiling water, but sometimes cold water was used. There was no boiler. Wooden tubs were used for the milking. The milk was set to cream in the shop. When we saw it the cream was standing in the close atmosphere of a living room behind the shop.

Bye-laws dealing with the personal cleanliness of dairy workers are now in operation in Dublin. Mr. Watson told us that in the dairies milk cans are usually cleaned with cold water. The washing of cows' udders is very little practised.

A milk vendor in the City informed us that the straining of milk both at once after milking at the farm and also on its arrival in the City is a general custom. In winter the milk is removed from the sheds to the yard for the purposes of straining. Milk is not cooled in Dublin, neither is this done in the country at all generally, save that in hot weather the filled churns are placed in cold water by the farmers. Mr. Stokes, of Limerick, informed us that the butter manufactory with which he is connected issue no regulations as to the cooling of milk. They are useless. Farmers will not cool the milk, and many will not even strain it.

During our stay in Dublin we had the benefit of conferences with the Right Hon. Horace Plunkett, President of the Board of Agriculture of Ireland; with Professor Carroll, of the same Board and superintendent of the Albert National Agricultural Training Institute at Glasnevin; and with Mr. Anderson, secretary of the Irish Agricultural Organisation Society, to whom passing reference has been already made. We discussed, *inter alia*, the past and present part played by co-operative societies in Ireland in connection with the dairying industry—an industry which Mr. Plunkett has done more to foster and improve during many years than can be easily estimated. Mr. Plunkett has, since our visit, addressed the following communication to the secretary:—

"Dublin, 25th October, 1900.—. . . The purport of my reference to calving and winter dairying. . . was that preservatives in Ireland were not called for in the winter; that too little of our dairying was done in that season; and that owing to the scarcity of labour and capital, the cultivation and extra shelter necessitated by winter dairying was probably the obstacle to a change. Danish dairying is mostly conducted in the winter, and no preservatives are there used.

"Personally, I am opposed to the use of preservatives in food. It is admitted that preservatives are added for the direct purpose of poisoning or inhibiting the activity of living organisms. It is true that a quantity which will affect this purpose in the lower organisms that pro-

Appendix.  
—

duce decay in food stuffs is insufficient to visibly interfere with the functions of highly organised, healthy human bodies. The material must nevertheless be poisonous to living matter, or it is unworthy of the name of preservative. As I told you, preservatives in milk and cream disagree with me; but this may, of course, be an idiosyncrasy.

"But there is another important consideration which influences me in recommending that the use of preservatives in dairying be abolished. I am convinced that, in order to develop our dairy industry and to produce articles of first-class quality, the necessity for thorough cleanliness in all departments of dairying must be brought home to those engaged in the industry. But so long as preservatives are permitted as a substitute for cleanliness it will be impossible for our dairy instructors to make satisfactory progress. Briefly, the use of preservatives puts the careless and slovenly dairyman on a par with those who are careful and cleanly.

"I am quite well aware of the fact that, no matter how cleanly a dairyman may be, it is not possible to entirely avoid the presence of objectionable organisms in milk; but the recent developments and improvements in dairying appliances, particularly those for the pasteurisation and sterilisation of milk and cream, should amply meet all requirements and render the use of preservatives unnecessary.

"It has been argued that it is better for consumers to have milk free from bacteria and containing preservatives than to be supplied with milk undergoing decay. I wish to point out, however, that there is no record of persons having been poisoned by milk that has undergone change. On the other hand, in the neighbourhood of Glasgow and Edinburgh, there are a large number of dairy farmers who do not separate their milk, but who allow it to undergo fermentation and churn the whole mass. The milk is then sold in these two cities as an article of diet, which is much prized and, indeed, is regularly supplied at some of the best restaurants in Glasgow.

"I am of opinion that the dairy industry would be ultimately put on a better basis if the use of preservatives were disallowed. Butter-makers would then have to work up to a higher standard, and the improved quality of the produce, coupled with the knowledge that Irish butter contained no foreign matter, would unquestionably enhance its reputation.

"I am further of opinion that an interval of two years should elapse before the prohibition is enforced. This would be sufficient time to enable the butter trade of Ireland to adjust itself to the new condition of things.

(Signed) "HORACE PLUNKETT."

The growth of co-operative dairy societies and of the auxiliary stations in connection with them has been remarkable. Turning to the pages of the report of the Organisation Society just referred to, for the year ended March 31st, 1899, we find there the number of societies in existence on the 31st March in each year, 1895-1899, viz. :—

|                 | 1895. | 1896. | 1897. | 1898. | 1899. | Membership. |
|-----------------|-------|-------|-------|-------|-------|-------------|
| Dairy Societies | 56    | 61    | 83    | 123   | 153   | 20,844      |
| Auxiliaries     | 8     | 9     | 10    | 13    | 38    |             |

As regards 1899 the distribution, membership, and trade were as follow, the trade figures representing only those societies which furnished complete returns :—

| Province. | Societies. | Membership. | Trade.   |
|-----------|------------|-------------|----------|
| Leinster  | 21         | 1,547       | £ 37,110 |
| Munster   | 64         | 5,773       | 247,345  |
| Ulster    | 76         | 6,903       | 63,922   |
| Connaught | 30         | 6,621       | 52,937   |
| Totals    | 191        | 20,844      | 401,314  |

The total capital invested at the end of 1899 in co-operative dairying was £166,558. The societies in that year received nearly twenty-three and a quarter million gallons of milk, from which they produced

nearly nine-and-a-half-million lbs. of butter, or 4,177 tons. The farmers supplying milk realised an average price of 3½d. per gallon, the separated and butter milk being given back to them. Milk payments absorbed £354,596, and working expenses amounted to £46,081—roughly 11½ per cent. on the value of the output, which realised the large figure of £401,771. A net profit of £6,176 was earned on the year's trading. This is available for allocation among the members of the societies. The reserve and accumulated profit amounted to £13,648. The price received for butter was 9·83d. per lb.—a shade less than the price received in 1897, which was 9·89d. The average yield of butter from the milk was, however, a record, 6·46ozs. being produced from a gallon. At the time of our visit the societies had further increased to 240 in number, with an invested capital of £200,000, and an annual trade turn-over of upwards of one million pounds sterling.

It is to be noted that the Organisation Society deplore the scarcity of well-trained creamery managers and dairymaids. Dairy inspection and technical instruction are, however, in progress. The report already quoted says :—

"The reports of the Government dairy instructors and of our own inspector show that the creameries are becoming more alive to the necessity for scrupulous cleanliness, but in some cases this important detail does not receive the consideration which it is entitled to. A placard giving instruction to visiting committees of creameries has been issued to the societies calling attention to this matter, and also to the very important question of a good system of drainage, so as to avoid the risk of contamination by bad odours."\* (See addendum.)

Sir Charles Cameron was good enough to take us over the Albert Institute at Glasnevin (to which we have already made reference), in company with the manager, and it may not be out of place to state here the main objects of this institution, bearing as they do very closely on the purpose of our visit.

The Institute is owned by the Government, and was built in 1839, though the present dairy building was erected only in 1881. The Institute was under the Commissioners of National Education until April last, when it was taken over by the new Board of Agriculture. The primary object of the Institute was to train school masters in dairying and farming as well as in literary subjects. When the Dairy School was attached in 1881, female pupils began to be received.

The Institution is designed to supply instruction :—

- (a.) In the science and practice of agriculture.
- (b.) In the most improved systems of dairying.

**Training Institution.**—The Training Institution is situated on the farm. The buildings comprise dormitories, dining hall, lecture and school-room, museum, library, and laboratory; and an extensive range of farm offices and dairies fitted up with improved machinery and implements.

**Farms and Gardens.**—These are situated about three miles north of Dublin, and one mile from the village of Glasnevin, and contain about 180 statute acres, distributed as follows :—

(a.) An area of four acres (statute) is cultivated as a small spade labour farm, with the view of exhibiting a proper system of cultivating the vast number of small farms in Ireland. (b.) An area of 22 acres has been set apart as a farm of intermediate size, with a view of illustrating a system of farm management adapted to the circumstances of farmers whose holdings are large enough to give employment to one or two horses. (c.) The remaining portion of the land forms one large farm.

Only five cows are kept at farm (a.), 10 cows at farm (b.), and 30-40 cows at farm (c.); the first (a.) is set aside for the purpose really of affording an "object lesson" to those school teachers who desire to learn how to manage a small farm, and then return to their scholars with practical information.

The teaching arrangements afford to the students as large an amount of information as possible upon every branch of the business of farming, e.g., dairy husbandry, the fattening of cattle, the breeding and rearing of

\* Among the leaflets which the society have distributed are the following from the "Technical Instruction Series":—Instructions for sampling and testing milk and cream, cream separation, ripening and churning, co-operative dairying, auxiliary creameries, home rule in the dairy, pasteurisation of milk and cream.

different kinds of live stock, the various operations of field culture, the permanent improvement of the soil, etc. The instruction is further eminently practical, the students being called upon to take part, for a limited time, in the performance of every farm operation.

As regards female dairy students, some 60 of whom enter each session, and creamery managers, of whom about 20 enter each session, the following regulations obtain :—

**Dairy Students (Females).** (Fee, £3 for each session of six weeks; two sessions each year.)—Admitted for instruction in dairy management. They are at all times under the supervision of an experienced matron.

The course of training embraces—

(a.) Instruction in the principles of feeding cows, calves, and pigs; the treatment of milk and its products; and the management of poultry.

(b.) The practice of dairywork. The making of butter and cheese in large and small dairies, both with improved machinery and implements, and also with ordinary appliances.

(c.) Such other subjects as may be determined by the Commissioners of National Education, including needlework, cookery, etc.

The admission fee covers the expense of board, lodging, washing, and medical attendance.

Examinations are held at the end of the sessions, and certificates awarded to proficient students.

**Creamery Managers.** (Fee, £3 for interns, £1 for externs, for each session.)—Young men employed in, or about to be employed in, creameries, are admitted for a five weeks' course of instruction in dairying, which begins on 1st March each year.

The course of instruction embraces :—

(a.) Dairy science, including the analysis of milk, buttermaking, and cheesemaking.

(b.) The preservation of the health and the feeding of dairy cattle.

(c.) Practical dairywork.

(d.) Theory and practice of book-keeping and accounts.

After the expiration of six months from the close of the session certificates are granted on the following conditions :—

(a.) That the student has attended the full course, passed a satisfactory examination in general dairy practice, and shown proficiency in the management of appliances for making butter and cheese.

(b.) That a favourable report has been received from the Creamery Inspector upon the creamery with which the student is connected, in respect of cleanliness, tidiness, and efficient working.

In addition, there is a farm at Limerick, whereat pupils practise creaming, etc., in order to give them larger experience in butter-making than the farms at Glasnevin afford.

The Munster Dairy School and Agricultural Institute at Cork is also owned by the Government, and provides classes, practical demonstration, and instruction on much the same lines as the Glasnevin School. Skilled instructresses are sent from the Albert and Munster establishments wherever their services may be required under the following conditions :—

1. That a small local committee shall be formed, who will provide, free of cost, a suitable building, such as school-house, barn, or dairy, where practical instruction can be efficiently given.
2. That a sufficient supply of pure water and means of heating same will be available.
3. That a sufficient quantity of milk or cream will be available.
4. That all necessary steps will be taken to make known throughout the district the intended holding of the dairy classes, and an endeavour made to secure the attendance of an adequate number of students.
5. That an active woman will be engaged by the local committee to attend the instructress during classes, for washing the dairy utensils.
6. That in each district, where practicable, a committee of ladies shall be formed, these ladies to exercise care over the classes, and to see that suitable lodgings be provided for the instructress.

The application for the services of dairy instructresses must be signed by at least six farmers, who must be responsible for the fulfilment of the preceding conditions.

The dairy instructresses may also be sent to any district upon an application to be signed by at least six farmers, for the purpose of visiting the dairies, pointing out mistakes, suggesting improvements, and making butter with the utensils, or other simple appliances found available.

There are also male dairy instructors, who visit creameries, etc., and make suggestions as to improved methods of dairying, butter-making, etc.

At the Glasnevin Institute, the whole-milk from the farms is mostly sold in Dublin, only the surplus being used for butter-making. The cows are milked about 5 to 6 a.m. for the morning delivery, and about 3 p.m. for the afternoon rounds. It is the experience there that the older cows give the richer milk, but in less amount. Cows' udders are rubbed with a dry cloth, when the cattle are stalled. The hands of the milker are always washed immediately before milking, and as often as possible during the process. The cattle receive great attention. Milk vessels are cleansed by means of water heated by steam, and the milk itself is filtered through cloth and a special strainer. The cow-house is 100ft. by 30ft. by 14ft. high, and gives 1,000 cubic feet of air-space per cow. It has eight windows, 14 special ventilators, and five doors. There is a sunk trench for cow droppings, effective drainage for liquid filth, and the manure is pumped from the adjoining yard on to the farm fields. Each cow has her own water trough. The cows are in the fields from 10th May till mid-October, and during the remaining portion of the year the cows in calf are exercised daily, the time during which they remain in the open being regulated by their own inclination. As soon as they desire to return to the shed they are permitted to do so.

Some of the milk at the Institute is sterilised, after having been filtered through a cloth. The bottles in use for such milk are first heated to 212deg. F. They are then filled with milk and raised to a temperature of 196deg. F. in a steam auto-clave. The glass and rubber-band corks are automatically closed by a very ingenious arrangement, and water is let into the auto-clave until the temperature has been reduced to 60deg. F. The water is then drawn off, the bottles uncorked, and the milk heated up to 212deg. F., after which the bottles are again closed, and the milk once more cooled down to 60deg. F. Milk thus intermittently heated is found to keep for an indefinite period. It darkens in colour a little.

At the Glasnevin Institute butter is only made from surplus milk from the city rounds. The milk is separated, after being heated in an ordinary Pasteurising apparatus to 160deg. F. The milk is only momentarily at 160deg. F. Some of the milk is set in flat, tinned-iron pans, and the cream resulting is hand skimmed. The milk has been previously strained, but not cooled, at the Institute farms, which, however, are close at hand. The milk setting room has windows that open wide, and are fitted with gauze blinds for use in summer. If the heat is too great, the windows are closed and the pans syringed with cold water to keep the room cool.

The cream taken from the pans is placed in a can, and this again in cold water in summer, and in warm water in winter. Very little ice (some half a ton) is used during a year; cold water suffices for all purposes. The cream is cooled to about 60deg. F., and all the skimmed milk is used for cattle.

The butter is sometimes made entirely without salt; and in other cases is salted to local taste. A great many people are said to prefer butter made with  $\frac{1}{2}$ oz. of salt to the lb. Only 50 to 100lbs. are made daily, more for purposes of instruction than profit.

The Institute possesses a "Radiator" which is used on an emergency for the manufacture of butter by one continuous process. It is the Aktiebolaget Radiator of Stockholm. But it can deal with only 50 gallons of milk per hour, as against 400 gallons in a complete set of ordinary butter making plant.

We visited the Lucan Dairy premises in Dublin, and also one of the two farms owned by Messrs. Nash, situated at Lucan, ten miles out of the city. The farm is large, with some hundreds of milch-cows. The hours for milking are in the early morning, and from 5 to 6 p.m. Calving is regulated, so that the cows calve about October, just as they are going into their winter quarters. The cattle are let out each day in winter for a couple of hours if at all practicable. Natural green food is given them during the winter months. The tuberculin test is applied whenever deemed necessary. Each milker

Appendix.

has his own cows to attend to. He washes his hands before he begins to milk, and as often as he can be got to do so during the operation. Stalled cows have their udders dry-rubbed. The milk immediately upon being drawn is strained through three layers of cloth and a metal screen, and in winter is at once removed from the sheds. In summer the cows are collected at different parts of the fields, and milked there until the grass has become soiled. Each cart as it is filled with cans is sent to town. The railway transit is very good on the Great Southern and Western main line. The cattle which we saw in the fields were very clean. They were of varying breeds, Dexter (one gave 4.5 gallons of milk daily), Kerry, ordinary Shorthorn, Ayrshire (best milkers), and Poll Angus (the smallest yielders of milk).

Milk cans are rinsed with well water at the farm. The cowsheds are whitewashed three or four times yearly, a man being employed at the farm for the purpose of painting and whitewashing. One shed which we measured was 105 feet long. It was stalled for 31 cows, each beast having a space allotted to her of 16 feet long by 3½ feet wide, by 11 feet high, giving her 616 cubic feet of air space. The shed had ten roof ventilators, always open, and two doors. The stalls were disinfected with 'Jayes' disinfectant when necessary. There were trenches for cattle droppings, and effective drainage for liquid filth; manure was frequently removed to the large open space in the form of a quadrangle, along the sides of which the cowsheds were disposed.

A veterinary surgeon examines all the cows every two months or so, and any which may be out of health are isolated. No infectious disease has ever, it is stated, been found in milkers or their families. If it were found, the milk would not be used till all danger of infection had been removed. The firm have a medical adviser of their own; but no printed regulations as to milk supply.

Ninety per cent. of the milk dealt with at the dairy premises in Dublin comes from the two farms belonging to the firm, ten and thirty miles away respectively; the remaining 10 per cent. comes from small farms, where, as is the case at the other two farms, cans are rinsed in cold water. On the dairy premises in Dublin the cleansing of the cans is accomplished by hot water and mops, and by steam under high pressure. The lids of the cans are cleaned with a hand-brush.

All milk sold by the dairy, viz., some 1,300 to 2,500 gallons each day, is pasteurised. The milk is retailed at 1s. 4d. per Imperial gallon. It is some ten years since the milk was first pasteurised in response to a growing demand for good milk. No preservatives of any kind are used in the produce passing through the dairy, and no difficulty has been experienced in dispensing with them. They were used years ago; but have been discontinued for a considerable time. No bottled milk is yet sold, but the use of bottles is in contemplation. The firm does not, however, regard the bottling of pasteurised milk as a necessity. It may be mentioned that Mr. Nash has patented a churn with a close fitting lid, into which milk after pasteurisation can be passed without becoming contaminated by the air. The closely-fitting lid is so arranged that all air taking the place of the milk drawn from the churn tap must have first filtered through dry wool. The air originally in the empty churn having been sterilised. From this churn, householders could be furnished with pasteurised milk in the same manner as they are now supplied with fresh milk, and big establishments, such as hotels, etc., could be provided with a churn for their own use.

On receipt at the dairy, which is under the management of Mr. J. Craig, the milk is strained, filtered through two linen cloths, and then passed through a separator to be further cleansed. The cream and separated milk are then re-united, and pumped up to a pasteuriser, where they are heated to 165° or 170° F. for half an hour. In the next place, air which has been filtered through hemp and wool is forced into the milk at a temperature of 170°. The aerated milk subsequently passes into a can through a gauze bag, this latter contrivance preventing the milk becoming "churned" by its fall.

As regards the butter-making section of the dairy, the cream is separated at 167° F., and the separated milk is also pasteurised and sold. The firm make their own butter starters, Hanson's lactic ferment being added to sterilised skimmed milk; and the starter prepared in the usual manner. The cream stands thirty hours

before being churned, eighteen of which are after its inoculation by the starter.

To prevent waste, skimmed milk and any surplus of new milk are mixed and churned. Some butter results; but the churning is really done to obtain the butter-milk, which is in demand, and contains 0.6 per cent. or more of butter fat.

The butter when removed from the churns is placed in ice-water before being worked, and two to three per cent. of salt added before the water it contains is expressed. From 1.75 to 2.0 per cent. of salt are regarded as remaining in the finished article. After washing, the butter is stored in ice-chambers in bulk till next morning, when, being firm, it is made up into ½ lb. and 1 lb. packets, and again placed in cold store till sent out. It is all sold in Dublin.

The cream which is to be potted is also kept one night in cold store. It is all sold by dairymen, about 25 gallons daily.

Sir Charles Cameron told us that preservatives had been found in cream vended in Dublin (the Lucan Dairy not being in question), and we found one dairyman in the city who admitted the use of "Articanus" for cream ordered in large quantities. Mr. Anderson informed us the Irish Agricultural Organisation Society have found preservatives in cream vended by grocers in Dublin.

As regards colouring matter Sir Charles stated that the common agent used, whether for milk or butter, is annatto. He thinks that no deleterious colouring matters are now employed.

#### *A Source of Cream Supply to England.*

We visited one large inland establishment whence cream is and has been for twelve years past sent to England in amounts varying from three to twenty churns three times a week all the year round. The milk for creaming is obtained from some 200 farms in the neighbourhood, none being more than six English miles distant. The establishment is very strict as to the condition of farmers' churns, and the farms supplying milk are regarded as being as clean as any in Ireland. The farms seen on our drive of many miles to and from the establishment, however, sufficed to indicate that, as we found elsewhere in Ireland, there is room for much improvement in this direction. Milk is strained on reaching the establishment and tipped into a measure. It arrives to the amount of about 5,000 gallons daily from 7 to 10.30 a.m. A sample of each farm's supply is taken, and the average amount of fat in a month's composite sample forms the basis of payment to the vendors. From 1,200 to 1,400 gallons are separated each hour at 152° F. by "Alpha" separators. The separated milk goes back to the farmers. The cream is not as a rule cooled, but it is placed in cold water tanks in hot weather, large churns being used. These churns are washed in soda and water and left for next day's use, prior to which they are re-washed with the aid of steam.

The cream is sent 7½ English miles by road, in open carts, covered with sheets, the journey being made slowly, and occupying three hours. Thence by rail to Cork, and by steam packet to one of the English Channel ports, and again by rail inland, taking two days in transit, and arriving "to all intents and purposes" sweet at its destination, where it is pasteurised, where "some preservative may be added," and whence some issues in brown jars, and some in tins, much of it finding its way into grocers' shops, big hotels, etc.

As regards the treatment of the cream in Ireland there is clearly a suspicion that the farmers may at times add preservatives to the milk sent to the central establishment to be separated. The analyst told us that some farmers do, as a matter of fact, use them. He submits samples to the action of bi-chromate of potash, amyl alcohol, and sulphuric acid, and he says that the behaviour of certain samples in comparison with that of others leads him to the conclusion that occasionally a foreign substance is added by the farmer. He thinks there is some chemical combination which takes place. He finds these differences in summer more than in winter.

With respect to the treatment of cream before it leaves the establishment, we were variously told that the use of preservatives had been dispensed with both in summer and winter: that formalin was once

used, but is not used now; that preservatives were tried and did not answer; and that some method of chemical preservation, the secret of the manager, was now in use, unvarying in winter and summer.

#### *The use of Preservatives in Butter.*

With reference to the use of preservatives in butter, we obtained a good deal of information from several different sources. In the first place, we learned from Mr. Anderson that butter which secures first prize at the Irish butter exhibitions is never preservative. He deems preservatives, as we have said, to be unnecessary for butter or milk. On the other hand, Alderman Dale, of Cork, who is President of the Butter Merchants' Association, still holds the view expressed in his evidence before the Committee that butter that has to be kept must be preservative in some way. Mr. Thorp, of Limerick, an expert on butter, thinks very little difficulty would be felt in the Irish trade if the Committee's findings led to the prohibition of boracic acid. In his view the absence of a definite pronouncement on the matter is the real trouble; that the laying down of some absolute requirement is what is needed, and would suffice as long as pasteurising is practised. He regards the use of preservatives to be wrong in principle, and opposed to the interests of the public health. Mr. Roche, of Limerick, who is intimately associated with Mr. Plunkett in agricultural reform, is of opinion that three years should be allowed to elapse before the actual coming into operation of any law prohibiting the use of preservatives in butter. They can be dispensed with, and "their prohibition would wipe out the dirty farmer," whose withdrawal from the butter industry would be in the best interests of the country. The present condition of dairy farming in Ireland renders preservatives necessary, and he (Mr. Roche) is well able to judge of the ability of Ireland to do without them since he has opportunity in his business relations of seeing butter coming from one hundred creameries; while as regards quality, he has the judging of the output of about two hundred creameries. His experience of the creamery system of the country has extended over five years.

Prof. Carroll told us that the farmers on the hills do not use "preservatives," but a "hot pickle" and much salt. Mr. Lough, of Killeshandra, has been sending butter to England for some years with less than one per cent. of salt, and without any other preservative whatever. Such butter is much in demand.

We spent some time with Mr. R. Gibson, salesmaster in Limerick Butter Market, and himself a vendor of preservatives. He showed us butter from various parts of the district, near and far. The following is a copy of notes taken at the time of our conference with him:—(1) Butter sent from East Kerry, with 3lbs. of salt and 1lb. to 1lb. of preservatives to 112lbs. will keep perfectly well for a fortnight, a time quite sufficient for all trade purposes. (2) Butter from co. Tipperary, made by a Dane, without salt, with 1lb. of preservatives to 112lbs. will keep a fortnight. (3) Butter from West Kerry, without preservatives, but with 3 per cent. of salt, had already begun to go off, being only three days old. This latter butter was not sold; merchants have been shy of buying it. Butter from near Tipperary town, with 1lb. of preservatives and 3lbs. of salt to 112lbs. (5) Butter made by farmer with his own separator. No steam power. The farmer earns more money by making his own butter than by sending his milk to a creamery. One small farmer makes £9 a week during nine months in the year out of a weekly output of 224lbs. of butter plus his butter-milk. (6) Butter with 1lb. of preservatives to 112lbs., but without salt. Said it would keep a fortnight. We did not like its taste. (7) Butter from a farmer 23 miles away on the hills in co. Tipperary made from skim milk without preservatives, and 4-4½ per cent. of salt. We did not like its taste. (8) Blended factory butter made with 5lbs. of salt and lb. of preservatives to 112lbs. of butter. Will keep at any reasonable temperature for three months, and still retain its original flavour.

We saw blended butter being worked up, after having been table-worked, by platter and hand, to still further express the butter-milk. All tub butter coming into Limerick is scraped to clean its surface. The scrapings are melted by Mr. Gibson and churned into butter, perfectly flavourless, for use in confectionery. Without the use of preservatives this butter would, Mr. Gibson stated, turn rancid.

3017.

Another butter seen was made by a farmer with a hand separator and yet another was an imperfectly worked butter presenting a streaky appearance, and this butter sold for 1d. per lb. less in consequence. The streaks indicated that neither the salt nor the preservatives were uniformly mingled throughout the butter substance.

As regards the use of hand separators by farmers, Mr. Gibson told us that farmers make some 30s. per cow per season more if they separate their milk for butter making on their own premises instead of sending it to a creamery.

#### *The Keeping Powers of Irish Butter.*

On the vexed question of water in butter as affecting its keeping quality and its weight, Sir Charles Cameron holds that anything over 16 per cent. is excessive, and advises proceedings against the vendor. The Dublin Bench convict when over 18 per cent. of water is found. Sir Charles gave us the following data obtained from a series of experiments conducted in 1894, as regards the proportion of samples of tested butter yielding over 16 per cent. of water from each of the four provinces:—

|           |   |   |             |   |   |                |
|-----------|---|---|-------------|---|---|----------------|
| Munster   | - | - | 604 samples | - | - | 42.4 per cent. |
| Leinster  | - | - | 179         | - | - | 13.4 "         |
| Ulster    | - | - | 50          | - | - | 8.0 "          |
| Connaught | - | - | 52          | - | - | 17.3 "         |

Mr. Stokes, of Limerick, regards upwards of 15 per cent. of water as detrimental to the keeping quality of butter; whilst Mr. Gibson went so far as to say that 17-18 per cent. is needed to keep salt in proper solution.

On the subject of the keeping quality of Irish butter, Mr. Anderson maintains that ordinary butter will keep as well as butter made from pasteurised cream if the cream be churned at the proper degree of acidity.

Alderman Dale thinks Irish butter has keeping properties equal to that of Danish, but it has not the same ready sale. Ireland "lost the market" before preservatives began to be used; the non-use of preservatives would, he alleges, lead to the flooding of the market at certain times of the year.

Mr. Stokes, of Limerick, tells us that creamery butter will keep for a month—that is, twice as long as trade purposes require. But Mr. Roche thinks a month requisite for the trade. Mr. Gibson says farmers on the hills keep their butter from July to the succeeding January, and then get top prices for it. A butter merchant informed us that he had purchased butter that had been stored for months under the beds in farmers' houses to avoid theft, which would probably have occurred had the butter remained in an outhouse. Some of these farmers, he says, only get to market three or four times a year, and could not cart their milk to a creamery. Professor Carroll, however, sees no difficulty in the way of transport; the butter held up in the way described is, he stated, very heavily salted, "hot pickle" being used for the purpose.

Mr. Lough, of Killeshandra, keeps butter in his cooling chamber at a temperature of 35° F. for eight days in hot weather, and then disposes of it. It sells as well as perfectly fresh butter, and is sent to London, a journey of two to three days.

With regard to cooling chambers for butter storage, at Cork we went over the Cork Ice Company's premises. This company has a large cold store for butter, and makes daily 6 tons of ice, 10 cwt. being turned out every two hours in cwt. blocks. The ice, which takes 24 hours to prepare, is extremely clean and transparent. The machinery is worked by electricity, and the water used is that supplied to Cork, but specially filtered. There is a winter store of 300 tons, and 40,000 cubic feet of storage space. One chamber is kept at 25° to 28° F., and ice and butter alike are stored therein; other chambers are at lower temperatures. There is non-conducting material in the double walls, and also 1½ inch of air space left free. Creameries also purchase the ice.

#### *The Condition of Irish Farms.*

The condition of the farms generally in Ireland, so far as we saw them—and we saw many in various parts of the great butter-making counties in the south-west and south of Ireland, and in the county of Cavan—was in no sense creditable from a sanitary standpoint. The examples of cleanliness were few and far between. Save in extremely few cases, the bedding in the shed, was old and offensive, both in those cow-houses which were totally covered and walled, and in those which

P 2

Appendix.

## Appendix

were partly open. The accumulations of manure in the yards gave evidence of long standing. In farms whence butter was being sent to market, creaming room and churning room alike were often in a by no means cleanly state. One very significant statement, made to us at times, was that the creameries do not know the conditions of the farms from which the milk received by them is brought. Nor do the factories know under what conditions the butter is made which comes to them for blending or tubbing. Neither could we find that much thought had been given to the question. Hence farmers have not had the incentive to cleanliness which would have been given if adequate inquiry had been instituted by creameries and factories into the actual state of farms sending milk or making butter, and if pressure to rectify offensive conditions had followed such inquiry and preceded acceptance of produce. The fact remains that those farmers who have been careless in regard of cleanliness and of the sanitary condition of their premises have in no wise suffered in a monetary sense. As an example, we may say that, perhaps one of the worst instances coming under our notice was that of a farm using the most antiquated methods, and yet this farmer obtained the top price in the local market for his butter. We do not say that all creameries and factories alike are negligent in regard for the source of milk and butter received, but the rule holds good generally. This is not the case with reputable firms vending milk as such.

We quote notes taken of the state of a few of the farms seen by us in sundry districts during our stay:—

(1) Farm, near Limerick.—60 acres, 23 cows; £25 given for hand separator. Now making 168lbs. of butter per week, salt and preservative mixture supplied by butter merchant; 2lbs. of mixture used to 55lbs. of butter. Water supply from pump in field near by. Mouth of well raised above level of ground. Cowshed very dirty, floor being littered with filth. House in which the milk is separated and butter made, deplorably dirty.

(2) Another Farm near Limerick.—200 acres, 27 cows, 185lbs. of butter made per week. Price better by 21s. per cwt. now than when the cream was sold instead of using a hand separator. Latter cost £26. Calves also better now that the farmer is able to give them skimmed milk quite fresh. We were informed that about 0·8 per cent. of butter fat was left in hand separated skim milk, and 0·2 per cent. with the Alpha separator. Separator cleaned twice a day, and milk strained into a tub immediately on being drawn; milk twice strained, and still dirt left in it. The farmer gets 20 per cent. more butter than when he allowed the milk to set and hand-skimmed it. In the season he finds a difference of £2 per cow, whether milk be sent to a creamery, or made by himself into butter, in favour of the latter. He has to get his water from a distance of 500 yards, and to water his cattle 400 yards away in another direction at a stream. It takes half an hour with donkey traction to get a tub of water from the pump. His custom is to keep and to milk his cows in the open during nine months of the year, confining them to their stalls during the night for the remaining three months. In winter, milking is done in the sheds, but he does not believe in shed milking. The conditions of this farm were distinctly above the average.

(3) Farm near Tipperary.—A farm of 50 cows, where the farmer makes his own butter in summer, but at the time of our visit he was merely sending the milk to a creamery. The churning and creaming room has a cemented floor; all contents very clean; but room opens from the large living room.

(4) Another farm near Tipperary, where butter which fetches top price of £3 3s. per 70lbs. was being made and sent into the Tipperary market; the churn was being worked by a donkey. Milk set for creaming under very dirty conditions, the smell of the house being foul, and the dirty water on the floor adding to the foulness. Owner uses 3lbs. of salt and 3lb. of boracic acid\* to 70lbs. of butter. In the heat of summer, a preservative is used both for the milk before setting it to cream, and for the butter when made. No preservative used in winter. The butter will keep for twelve months, even without boracic acid. The whole place was indescribably dirty.

(5) Farm near Limerick Junction.—There are 64 cows, and the milk is sent in to a creamery once

a day, the evening milk being set in churns in a cold water tank in the yard. Cows are in the sheds from January to May, but are exercised every morning for a few hours when weather permits. Cowsheds were somewhat cleaner than in general, and had the usual permanent side openings. No preservative is ever used in milk.

(6) Small farm near Tralee.—Farmer keeps 20 cows; butter sent away fresh, without salt, to Tralee, once a week. Cream set in shed with dirty floor. Bird and poultry dropping, etc., on floor. Butter washed three times in water.

(7) Farm near Tralee.—Farmer keeps five cows; butter sent to local customers. Very dirty floor to storehouse for setting cream and for butter making.

(8) Farm near Tralee.—Farmer keeps 49 cows; makes his own butter, which is sent to England through an agent. Uses a handful of preservative to 56lbs. of butter, and 2lbs. of salt; and sometimes sugar also. Very dirty cowhouses, wherein the cows are always milked, and house for storing cream and for making butter also very dirty. Stone flooring to store room. Farmer strains the milk and cools it by water in the sheds. Water from well.

(9) Farm near Tralee.—No preservatives used, but 3 per cent. of salt. The cream is left on the milk till the milk turns sour. Farmer churns twice a week. The cream is kept a week in winter or till it goes sour. The creams of different days are mixed, each three days' cream together in summer, and each six days' in winter. The resulting butter is regarded as of first quality in Cork Butter Market. The butter is known to go to England also. He gets the best prices, and no complaints have been received. It goes first to Tralee, but is not blended. The milk for creaming is strained immediately after being drawn, and is taken from the cow to a large tub, where it rests for an hour. It is then left in the setting pans. The screening is done through muslin over a metal-gauze strainer. The butter is worked by wooden platters. The water supply is from a well a quarter of a mile away. The water in the house is not fit for domestic use, or for butter making; it has too much iron in it. The cows are milked in very dirty cowshed, but with plenty of air space round it. The shed has a wooden roof, and was covered with cobwebs. The floor of the shed in which the cream sets was dirty, but concreted. The shed was clean. The open yard was dirty with old manure, and there were recent cow droppings. Milk vessels are cleaned in boiling water, in a boiler in the house, for 20 to 30 minutes, and then dosed with salt, and rinsed with cold water. The butter will keep for three weeks with only 3 per cent. of salt in it, even in the heat of summer. No preservatives were used.

The farms seen on the way to Belturbet from Killeshandra in Co. Cavan were very dirty, both as to sheds, mud floor, yards, and milk storehouse. We saw several of them, and all were alike in the matter of filth. And this despite some attempt on the part of the creameries hereabout to get the farmers to adopt habits of cleanliness.

We inspected one of Mr. Lough's cowsheds near Killeshandra, at 9 o'clock one morning. The cows had, as usual, been milked in the shed in the early morning, and the droppings of the cattle had not yet been removed. But the shed was well arranged and ventilated, and had at the time the smell of a well-kept cowhouse. All manure is removed as one of the stableman's first duties each morning, but on this occasion the shed had been left as we found it until our inspection was made. The milk of each cow is immediately removed from the shed, which latter has its wooden stall sides white-washed frequently, as often as once a month in winter. The floor of the shed is constructed of wood beneath the forefeet of the cattle, and of concrete under their bodies. There is a trench for the droppings and liquid manure.

*Certain Considerations Relative to Irish Dairying.*

Before proceeding to describe the methods adopted at the several provincial creameries and butter factories in relation to preservatives, it may be well to refer to a few expressions of opinion which we heard with regard to the pasteurising and sterilising of milk, and as to the regulation of calving, and of winter dairying. Mr. Thorp, of Limerick, regards the sterilising of milk as producing a bad flavour in the milk, whilst if pasteurisation were made compulsory all the creameries in the South of Ireland would, in his opinion, need to replace their plant. This statement seems to us to require some modification in view of the fact that pasteurising

\* The boracic acid had been sold to the dairymaid as butter powder, "containing no acid."

is already—though certainly to a limited extent—practised in the South. Professor Carroll is of opinion that the practice will grow. Alderman Dale and others told us that, as a general rule, calving is not regulated in Ireland. There is lack of organisation. Here and there we found some attempt being made, and again, firms which deplored their inability to secure co-operation in this matter on the part of farmers, occasionally set the example as regards their own local herds, as in an instance to which we refer later, near Waterford. Moreover, great hopes are entertained that the new Board of Agriculture will do something to foster the practice. With regard to winter dairying, for an extension of which in Ireland great need exists, Mr. Shanahan, of Cork Butter Market, told us that there is abundance of grass from May to October; but that farmers let their cows run dry when food becomes more expensive, attaching more importance to the extra cost of winter feeding than to the profits of butter making. A little inferior butter, he says, is made as late as December, and then practically none till April. In the county of Limerick, with the richest land in Ireland, the creameries have, he remarked, to be closed from November to April in each year because of the scarcity of milk. Yet at a farm making its own butter, near Limerick, we were told by the owner that on food costing 8d. per cow per diem his cows produce four gallons of milk all the winter. And Mr. Roche, of the same town, states that winter dairying is on the increase, especially in the North.

It would appear to be a widely prevalent opinion that Ireland is losing much to-day by reason of lack of initiative on the part of her farmers in the direction of regulated calving and consequent winter butter making. The Irish Agricultural Organisation Society is doing good work in these matters, but the hearty co-operation of the large numbers of cow-keepers who at present are inactive in this regard is needed to place the butter industry of Ireland on a better and more secure footing. The small amount of winter dairying in itself tends to prolong the necessity for a "keeping" butter which consignees of Irish manufacture have come to look upon as a natural produce of the country, and hence the use—as we were generally told—of chemical preservatives.

It will be seen from the following examples how varying are the methods employed, quâ preservatives, in the manufacture and blending of butter in Ireland. The practice in this regard varies from the entire absence of preservatives in butter made from unpasteurised or pasteurised cream to the addition of as much as  $\frac{3}{4}$  per cent. of such preservatives. Messrs. Cleeve, coming between the extremes, use only  $\frac{1}{2}$  oz. for each cwt. of butter at Tipperary, and through the major part of the summer none at all. Again, it will be noticed that in the past very much larger amounts of these substances were added by certain of the manufacturers than is the case now; no inconvenience is found to attend the use of the smaller quantities. One firm declared that for some seven years no preservative whatever was used by them, then two or three per cent., and now less than one-half per cent. We think these facts need but little comment.

#### *Notes as to Creameries and Butter Factories.*

I. A Creamery at Tralee.—The milk is brought into the town in wooden buckets by donkey cart. The buckets have wooden lids, which are enveloped in a linen cloth, and by this means are made to fit tightly. Ordinary churns are occasionally used. Milk arrives during the morning, about 120 carts coming distances of some three miles on an average. Only whole milk is dealt with. Each farmer's milk is separately weighed before being passed through the strainers into the general supply contained in a drum-shaped receptacle. The milk from this drum passes into a tank, and is warmed in winter time up to about 80° F. to facilitate the separating process. In summer the natural heat suffices. Its temperature upon arrival at the creamery building has been known to be over 70° F. The milk on the day of our visit was 76° F. The milk which is brought each morning to the creamery consists of the same morning's and the preceding evening's milk, the mixture between these two being effected at the farm. From this it follows that some of the milk upon arrival at the creamery may be sixteen hours old. The first strainer kept back much dirt, as did also the second (upper) strainer. A pocket knife and a watch, we were told, had been found in the first strainer on different occasions, and we saw, both here and elsewhere, ample evidence of the necessity for such straining. The milk is never cooled at Tralee,

but the churns are during summer placed in cold water at the farms in the evening. There is no pasteurising practised. The cream is set for 24 hours in cold water tanks, and then churned, the act of churning occupying about half an hour. No salt is added for mild butter intended for Bradford, Southampton, and the local trade; but  $\frac{1}{4}$  per cent. of boracic acid is used, even in the heavily salted butter (3 per cent.). Pure boracic acid is used mixed with the salt, the mixture being applied by hand. The dairymaid stated that as she was able to exactly estimate how much she is adding, she does not weigh the actual mixture. She takes three handfuls to 56 lbs. of butter. We tested her ability:—

|              |              |                     |
|--------------|--------------|---------------------|
| First time - | 3 handfuls - | $1\frac{1}{2}$ lbs. |
| 2nd „        | „            | $1\frac{1}{8}$ „    |
| 3rd „        | „            | $1\frac{3}{4}$ „    |
|              |              | full weight.*       |

The butter is never handled. Some 13 to 14 per cent. of water is left in the finished product. Butter sent out on Saturday would be in consignees' hands in England on Monday evening. It can be in England 24 hours after making. It will keep unsalted for 14 days, and for a month if salted, assuming that preservative be added in each instance. No butter is sent out without preservative. It would "go off" after four days.

The separated milk is weighed and returned to the farmers, 10 per cent. being deducted for cream taken for butter-making. The farmers are paid for their milk on the average of butter fat in each month's milk as ascertained by multiple samples.

The well is in the yard. Its water is used for cleaning cans. The well is open to surface pollution, and is dangerously near a manure heap.

The farmers, we are told, cleanse the milk cans in boiling water.

II. A Butter Factory at Tralee.—In the factory butter 6 lbs. of salt are added to 70 lbs. of butter. There is no blending of salted butter from the farms. The only blending is of unsalted butter bought in the usual markets and coming in an unfinished state. Preservatives and salt are used in factory butter after its arrival at the factory, and it is alleged that neither are added prior to this. The unfinished butter arrives from the farms in tubs or firkins, and as an example of the common practice we were told of a farmer who, by means of two churnings, is able to fill a tub each week. The butter is classified, and the classes blended, each class by itself. There are two classes at this factory. Our visit being on a Saturday, no blending was in progress. The boxes in which the butter is bought in the markets are covered inside with cloth. The butter is sent in bulk in these boxes.

The butter-table upon which the butter is worked up was fitted with a large tooth comb used for freeing the butter from hairs, etc. Butter is worked for six minutes, 5 cwt. at a time. The factory now uses  $\frac{1}{2}$  per cent. of boracic acid in place of 1 per cent. which was formerly added. Salt and the acid are mixed, and put in after weighing. The acid costs 29s. 6d. per cwt. (5 cwt. bought at a time), and 1 lb. of boracic acid goes to 14 lbs. of salt. Each lot is measured. The colouring for the low class butter is Mallen and Co.'s, of Dublin, Patent Oleo Butter Colouring, and was, we were told, recommended by Professor Carroll. The butter to be coloured is left longer on the working table than if no colour be added, an extra three minutes being allowed.

III. Manchester Wholesale Co-operative Society, Tralee.—The Manager, Mr. Dawson, told us that no colouring is used in the butter. There is from 5 to 7 per cent. of salt in farmers' firkin butter. The creamery butter is bought from local creameries. Preservatives are used. The Society has here a creamery, factory, and butter agency in one. They put  $\frac{3}{4}$  per cent. of boracic acid into factory butter, i.e.,  $\frac{3}{4}$  lb. of boracic acid and 2½ lbs. of salt to 112 lbs. of butter. Each 112 lbs. of butter going on the table is estimated as such, but the mixture of salt and preservative is actually weighed. Some few years ago 2 per cent. of boracic acid was used; prosecutions in England led to a reduction to  $\frac{3}{4}$  per cent. plus 2½ per cent. of salt.

The milk of each farm is tested daily. The milk is heated to from 100° to 110° F. before it is separated, and the skimmed milk is pasteurised before sending it

\* This same dairymaid could not in many instances tell the amount of butter going to 1 lb. at all exactly.

## Appendix.

back to the farmers. From 0·3 to 0·5 per cent. of butter fat is left in the separated milk. It is pasteurised to about 180° F., and the plant can deal with 800 gallons per hour. The milk is then cooled to about 60° F. The Society deduct 15 per cent. of the skimmed milk from the farmer in respect of cream taken. For the creamery butter no cultures are used, the cream being allowed to ripen automatically. The Society churn seven days a week. The cream stands 24 hours, before being churned. All vessels are cleaned by hot water. There is an ice-making apparatus, and in addition another machine for cooling water. The floor of the well-appointed buildings is cemented.

In Mr. Dawson's view Ireland could not to-day supply the demand for winter butter if boracic acid were not used. Factory butter would suffer most if preservatives were prohibited. The question is one of the regulation of calving. There are some districts, he said, where it is certain that creameries will not oust factories.

IV. Messrs. Lonsdale and Co., Cork.—Here all cream from 30 auxiliaries is pasteurised under the direction of a Swede, who learned his dairying near Malmö. The oldest milk used is in summer that of the previous night, and in winter that of two days ago. If "fresh" cream—i.e., cream under a certain degree of acidity—is not likely to be obtained from the milk the milk is sent back to the farmer. Cream from milk too sour will not make good butter after pasteurisation. Milk must be kept sweet. All milk is tested to ascertain its condition for pasteurising. Butter is sometimes made from milk that is a little sour, but the butter is of inferior quality. It is of the greatest importance that the cream used for pasteurising shall be perfectly fresh, the object of such pasteurisation being largely to enable the souring of the cream to be brought about by the use of artificial culture. If natural souring is allowed to take place prior to pasteurisation it is impossible to get rid of the sourness thus produced by the subsequent pasteurisation. No preservatives are used; none are considered necessary in pasteurised cream. The firm make the finest grade of butter with  $\frac{1}{2}$  lb. of salt to 112 lbs. Their assistants come from Lombardstown Creamery, where they received instruction at the hands of an experienced man.

In the act of pasteurising one of two methods is adopted. Either the whole milk is pasteurised at once, or the actual pasteurisation is confined to the cream, which is raised, and kept at, a temperature of 187° F. for at least five minutes. Butter thus made will keep for two to three months, with 3 per cent. of added salt, and with  $\frac{1}{2}$  per cent. of salt will keep two to three weeks. The best butter is only once worked, the salt being added at the time of working. Other butter with 3 per cent. of salt is partially worked one day, and completely the next. Hanson's lactic ferment is used for the preparation of the starters which are made from sterilised milk in the usual fashion; 12 gallons are added to 200 gallons, i.e., 6 per cent. of the starter, which is made the day before use. There is 11·2-13·5 per cent. of water in the finished butter. The added salt is sprinkled on by hand. No colouring matter is used in creamery butter, but it is added to factory butter to suit local fancy. The firm have no detailed control over the auxiliaries; but, according to the regulations, no preservatives may be used by them.

The firm also have a butter factory. All butter received for blending must be unsalted on arrival at the factory. They use 0·75 lb. of preservative in each cwt. of factory butter. Salt and preservative are weighed separately before being added to the butter. No annatto is used, the colouration being produced by a solution of aniline colouring matter in cotton seed oil. The butter is kept in a cold chamber at 32-34° F. for periods varying from 2-5 months. Both preservative and unpreserved butter is stored, some with 3 and some with 1 per cent. of salt. There is found to be only a slight difference between butter sent out at once and cold stored butter.

V. Mr. Shanahan's Butter Factory, Cork.—Mr. Shanahan uses a preservative mixture of borax, boracic acid, saltpetre and glycerine; of which 0·75 per cent. is mixed with salt. He has a special butter worker invented by himself for turning the butter on the table. The conditions under which his factory butter is made are not known to him. He has issued no regulations as to farms. He has three classes of butter. He showed us a cold chamber at 37° F., and another at 36° F. He sends tinned butter to Africa, South America, various shipping companies, etc. It will keep

for 12 months with  $3\frac{1}{2}$  per cent. of salt and 0·75 per cent. of preservative.

VI. Messrs. Cleaves' Creameries.—(1) Limerick.—All milk is heated to 110-120° F. before being separated. There are twelve separators. The separated milk is condensed. The cream passes over two coolers, one at 54° F., and one at 23° F.; and it is then kept in a cool chamber. There is no pasteurising in summer, but it is practised in winter. There is no handling of butter on the workers. A butter-milk starter is used. Only 1oz. of preservative and 1·3 lbs. of salt are used to each cwt. of butter. Salt is added up to 3 lbs. per cwt. according to the taste of the local market to which it is going. During the summer no preservative is used, nor on this account is the amount of salt increased. No complaints were received last year till September, when the preservative as above began to be used. The butter is salted at the first and only working, after the butter-milk has been expressed by a few revolutions of the table. The butter-milk is strained on leaving the churns. All separated milk is boiled for half an hour prior to being condensed at low pressure in a special apparatus, and no preservative other than sugar is used in the condensed milk. The firm have 24 receiving stations for milk for their five large creameries, the separation taking place at these collecting centres. All the milk is strained on arrival at the central creameries. While watching the process of straining, we saw among the debris from the milk, *inter alia*, a large slug and a milker's cloth.

(2.) Tipperary.—No preservative was added to the butter during the whole of last summer, until the second week in September, and no additional amount of salt was used. The butter is worked on the table before the addition of the salt and preservative. It is then twice washed in cold water. Only 3 ozs. of preservative are added to 6 cwt. of butter. All instructions come from the Limerick establishment. No complaints had been received last year until September, and then only a very few. The preservative and salt mixture is put in by the hand without weighing. There is no exact weighing of the ingredients. While we were present the dairymaid put  $5\frac{1}{2}$  lbs. of mixture on 200 lbs.—approximate—of butter. The mixture was weighed for us, and was found to be 2 ozs. of preservative to  $9\frac{1}{2}$  lbs. of salt; this being the proportion which the dairymaid had mixed, not knowing our intention to have it weighed. No ice is used, only cold water. The cream is set for 24 hours, all the year round, in a regulated temperature. There is a cooling chamber for setting cream, worked on the ammonia system. The firm have issued a strict order that evening milk is to be cooled on the farms. The creamery is working seven days a week.

We saw one of the cream collecting stations belonging to the firm, where the milk of 64 farms (1,200 gallons) is separated each day, and the cream sent in to the Tipperary establishment. The residue left on the strainer by 1,200 gallons was very small, suggesting that the farmers in this district strain the milk well. The milk is heated to 110° F. before being separated. The station was the first creamery set up in the district before its present restricted use. Its water supply is from four wells, which are said to furnish good water.

VII. Mayfield Dairy, Portlaw.—Two hundred and fifty farms send their milk twice a day in summer to this dairy. The total amount is about 4,000 gallons daily. The cans are washed by cold water and scalded by steam at the dairy. One and a quarter lb. of preservative and 3 lbs. of salt (or none at all—to taste) are used to each cwt. of butter. The preservative does not vary in amount. The butter goes to Waterford by road—12 English miles—and thence to Bristol by steamship.

VIII. Co-operative Creamery just started at Piltown.—The creamery had only started on the day of our visit. No butter had yet been made. Nine hundred £1 shares had been taken up; the initiative, we were told, lay with the parish priest, from whom, unfortunately, we failed to learn more of the facts; this we regret, as the information would have been of interest in view of the statements made to us by different traders that such local creameries could not be set going in the South of Ireland.

IX. Killesandra Creamery, County Cavan.—Here  $\frac{1}{2}$  lb. of preservative is used per cwt. of butter, and salt to taste. Milk is not pasteurised. It is heated to 100° F. before being separated. Milk is brought to the creamery direct from farms, and also from seven auxiliary creameries. There are 240 people sending direct to the creamery, and the number of farmers contributing amounts to 1,000.

X. Ballyhaise Creamery, Co. Cavan.—This was opened only in June; no preservatives had been used since August; further, the salt had not been increased since discontinuing the preservatives. Their motor power is water only, consisting of a very large water wheel, which gives never less than 50 horse-power. For heating milk and water a steam boiler is used. In future they will pasteurise cream as it comes from the auxiliaries. The water for cooling is pumped up from a well, yielding water at 53° F. in hot weather. They make their own ice, and have a large cold store chamber. There is a cement floor in all parts.

We saw some of the "skimming stations" where milk is separated and from which the cream is sent to the Cavan Creameries.

Crossdoney Skimming Station.—The cream is sent to Killeshandra. The station has double walls and roof, with empty air space, and a concrete floor. The receiving tank is heated from below, milk being raised to about 100° F., to facilitate separating. A pasteuriser will be put in this year at a cost of £50. On the day of our visit 738 gallons of milk had been separated. The separated milk is returned to farmers. The cream is cooled by a cold water cooler, and the vessels are cleaned by boiling and steam pressure. The station was set up in June, 1898. A sample of the milk is taken daily from each farm and examined weekly. It was one of the earliest stations set up in Ulster. Morning and evening milk is as a rule mixed.

Lossett Skimming Station.—This is a wooden erection with cement foundations and a corrugated iron roof. There is a hollow space in the walls and roof. Milk is separated at 150° F. The idea is in future to pasteurise whole milk before separation. There are two coolers. The cream goes to Killeshandra. The skimmed milk is sent back to farmers.

XL Creamery near Waterford.—Here "Douglas' Food Preservative Antiseptic" is used,  $\frac{1}{2}$  lb. to 112 lbs. of butter. The firm were in the habit of using 2 per cent. before the Cardiff prosecution case. For seven or eight years butter was sent out with no preservative whatever, and no more salt than now. They add from 1 lb. to 4 lbs. of salt per cwt. of butter, according to taste. They stated that  $\frac{1}{2}$  lb. of preservative plus  $1\frac{1}{2}$  lbs. of salt will keep butter for 10 days. The butter will then begin to "go off." The starter is made from butter-milk. The skimmed milk is taken by farmers. The farmers cleanse their own churns. The milk is weighed and strained on arrival and heated to about 90° F. in summer and 100-130° F. in winter before separating it. The cream is set in cold water tanks for 24 hours in summer. The temperature of the water used was 58° F. The cowsheds are used for milking all the year round. They have a cement floor, and were very clean and sanded with coarse gravel. They are also airy. There is sufficient space between the two rows of cows for a horse and cart to traverse the entire length of the cowshed, and the solid manure is collected in this manner. The liquid filth runs to one end by means of a sunk trench.

The Parcel Post custom of the firm is able to be kept up all the year round by means of regulating the calving of their own cows, 40 in summer and 40 in winter. The farmers in the neighbourhood cannot be induced to regulate the calving of their cows.

XII. Portable Creamery, Dunhill.—This structure will run from one station to another this year, separate the milk on the spot, leave the skim milk to go back to the farms, and the cream to go by cart to the central creamery. It is to be drawn by a traction engine of 5 horse-power through a very hilly country. The van has double walls and sides of wood, with corrugated iron covering. The inter-space is filled with silicated cotton. There is a concrete floor. The van was very hot inside, even with one end open, when we entered after it had been in use. There are a separator, a heater, tanks, etc., inside. The milk is strained on receipt, and cream and skim milk flow by different pipes to cans outside. The steam needed for the machinery will come from the traction engine.

#### MARGARINE.

We visited certain margarine factories in the course of our stay in Ireland. In every instance we were assured that preservatives, such as boracic acid were necessary in order to confer a keeping property upon the margarine. We were informed at one factory that on a certain occasion the preservative was

accidentally omitted, and the whole consignment was shortly returned to the vendor, owing to the occurrence of decomposition.

Appendix ix.

#### BACON.

We spent some time in the larger bacon factories seen in the course of our visit, being accorded much information on the subject of the manufacture of that article. But we reproduce here only such facts as are pertinent to the object which we had in view, namely, the question of the use or non-use of preservatives other than salt or saltpetre in the processes of cure and packing.

At one factory at Limerick they use only salt and saltpetre, except during about two months in the year, when they sprinkle a little boracic acid on the outside in the folds of the skin, to keep the fly away.

The manager of another factory at Limerick thinks that salt and saltpetre do not suffice for modern bacon curing. He puts preservative in the brine which is injected into bacon. He dusts hams with boracic acid when they are to be hung. He does not think the finished article requires to be packed in boracic acid. This bacon goes to all parts of the world without any refrigerating chambers being deemed requisite on board ship.

At a factory at Waterford they cure whole sides of bacon. Hams are not cured. They inject a pickle into the meat, composed of a saturated solution of salt and water mixed with saltpetre. This saturated solution is mixed with the red pickle draining from the meat, the pickle forming five-sixths of the whole at some periods of the year. Bisulphite of lime is used in the very hot weather only. This is sprinkled on the fleshy part of the side, and brushed lightly over the whole length to prevent fly-blow, and is washed off within 24 hours. It is used in very weak solution. It is not considered necessary to use any preservative in the cure. The bacon goes to London, and is almost all used in the United Kingdom. It is mild cured bacon. It goes by steamer from Waterford, packed in a clean part of the hold, but not specially packed. For dusting over the thick portions, just as the bacon is being packed, the firm use three parts of salt to one of borax. It prevents fly-blow and moisture. The mixture is rubbed into the flank of the hog, immediately prior to packing, all through the summer, but not in winter. Twenty gallons of red pickle, plus 3 gallons of bisulphite of lime and 15 lbs. of borax, are used during summer to fresh meat. This pickle is not used again.

At a factory a few miles from Waterford some preservative is used for bacon, in the injecting solution, which is composed of 8 gallons of water, 50 lbs. of salt, some sugar, 8 lbs. of saltpetre, and 4 lbs. of boracic preservative. The bacon is dusted for curing with salt and saltpetre. There is a cold store for bacon at 52° F.

#### RAILWAY AND STEAMSHIP TRANSPORT.

Great Southern and Western Railway Company.

The Goods Traffic Manager, and the Assistant Superintendent of Traffic of this company, whose operations cover almost the entire district of the dairying industry of southern and western Ireland, were good enough to furnish us with the following information:—

Wagons fitted with ice receptacles are being built for the carriage of butter from Limerick and other places. It is not yet settled who is to supply the ice. The wagons are to be provided with double sides and roof, and the floor is to be lined with felt, and to have air space also. The ordinary wagons with double sides but no ice are used for butter transport. They have a special air space, but as a rule no special ventilation. Very little difference as regards temperature has, we were told, been found experimentally, whether the vans be painted white or no. Butter can be put into wagons at once on reaching the principal-centre stations on the line, where the trucks stand until picked up by goods trains at night. Butter need not stand about the platform, but it may be in the trucks over twelve hours. Butter is generally sent by goods trains at night. It can be sent by passenger train at advanced freightage. The amount brought to Dublin was 2,213 tons from January to June, 1900, and 2,800 tons to Cork in the same period. During the

## Appendix

summer season a special Saturday night butter train runs via Dublin, to Holyhead, in connection with the L. and N. W. R. Co.'s steamers on Sunday morning, for a special market held at Manchester on Tuesday. The butter arrives 24 hours in advance of the market, the consignees keeping it till Tuesday in cold storage. The butter is sent fresh, with or without any salt, and is largely creamery butter. A steamer also leaves Waterford in the same way on Sunday morning for Liverpool for the Manchester Tuesday market.

Milk is all carried by passenger trains. A large quantity comes up from Cork by night mail. Milk vans, ventilated at each end, are used for churns holding 18-20 gals. each; the vans are whitewashed inside early each season. Some farmers send milk in open trucks by preference. Limerick is a large centre for both milk and butter. Farmers only send milk once daily, the rule being to mix the morning and evening milk. The morning milk is often 24 hours old on delivery to houses.

Dublin is chiefly supplied with milk from local farms. The company carried only 433,690 gals. in six months from January to June, 1900, for a population of 360,000 persons.

There is not much natural ice in Ireland. The transit of artificially-made ice from Dublin for storage by farmers would not be expensive. Farmers store but little ice now.

The company receive few complaints. Such as there are relate mainly to damage to butter on steamships.

We saw an ordinary milk van, which was whitewashed inside, and ventilated by upward slits across either end. Some butter wagons have double sides and roofs, no packing, two small ventilators, one on either side, and are whitewashed inside.

When at Mallow Station on September 18th last, we chanced to see a railway truck which was in use for milk and luggage. It had poor ventilation, and was foul smelling.

#### Midland Great Western Railway Company.

We saw Mr. Morrison of the traffic department, who told us that no special wagons have been built for milk or butter transport. There is no great traffic in these commodities. Butter is sent in dry wagons, and special instructions are given that the wagons must be in good condition when used for the carriage of dairy produce. The carriage of small family boxes is catered for at low charges in special boxes, as on many of our English railways. Butter goes by goods trains run at night. Milk is sent by passenger train. No complaints have been received as to either butter or milk.

We were given an introduction to the station master of Killeshandra, co. Cavan, from whom we learned that the night butter train takes 12 hours, 5 p.m. to 5 a.m., from Killeshandra to Dublin, 88 miles. It stops at Crossdoney Junction from 5.45 till 10 p.m. There are no special vans on the railway at present for this produce, and no provision is made for keeping fish, etc., from being placed in the same van as butter. Some 5-6 tons of butter are taken from the local creameries, and 2 tons from other sources, each week at Killeshandra Station. Straw or some dry material is put in the bottom of the vans. The same truck might carry butter one day and cattle another. The trucks used for cattle are whitewashed. The wagon would be very hot on a summer day before the butter was placed in it, having stood in the sun all day, unshaded.

#### Cork Steam Packet Company.

The officials of the managers' department informed us that the company have ten sailings a week—for Liverpool, New Milford, Bristol, Cardiff, Newport (Mon.), Plymouth, Southampton, and London. Their vessels are from 1,200 to 1,400 tons gross. The freightage for butter is 30s. per ton from Cork to London. Many complaints are received as regards butter sent by rail to inland places on arrival in England, but no complaints as to butter as landed at the port of arrival there. The butter is placed at once in a shed on being landed. Two of the steamers were fitted with refrigerating holds last year. They trade to Liverpool, and are highly appreciated. These vessels are 3-4 hours at sea before the cold chambers are reduced to a temperature of 40° F. The freights are not increased for these vessels. An increase of vessels fitted with such apparatus is contemplated. The managers are quite

satisfied that such chambers form the best means of transporting butter by steamships. It is three days' steam to London, and the butter traffic is not large.

Some butter that is shipped at Cork comes there by railway, and much of it goes on to the butter market before shipment. No butter stands on the quays.

Boxes and packages have largely taken the place of firkins.

The butter is stowed in the lower hold of the vessels, below water-mark, but if sent in small quantities it might be packed among other articles. Any clean material, such as oats, might be placed with the butter. The temperature of the hold never exceeds that of the air outside. The management feel strongly that butter should not be shipped in a soft state. It should be placed in cold store first.

Cream is also carried, in large churns, to Southampton for inland places in ordinary vessels, and no complaints have come to hand as to its turning sour. It is kept on the upper deck in a cool place. The cream comes from country districts in Ireland.

#### CONCLUSION.

We do not propose, as we have already stated, to deal with the subject of dairying in Ireland in all its varied aspects. It will, however, we think, be abundantly evident from the facts which we have furnished in the foregoing report that the conception which the average Irish dairyman possesses as to the advantages to be derived from cleanliness, straining, and cooling is not so complete as is that possessed by the Dane. Hence the Irish milk and butter dealers are at a disadvantage as regards their ability to dispense with the use of preservatives. The facts adduced demonstrate the practicability of the manufacture in Ireland, and the ready sale in England, of butter free from preservatives. There is evidence also that forces are at work in Ireland tending towards a better state of affairs, *quâ* cleanliness, in which the use of preservatives is less likely to be thought essential than is the case at the present time.

As bearing upon this aspect of the question attention may be drawn to the fact, amply illustrated in the foregoing notes as to creameries and factories, that there has been a very decided tendency of late in Ireland to reduce the amount of preservatives used, while in certain instances the use of these substances has been entirely dispensed with. It is instructive, too, to note that when a reduction in the amount of preservatives has been made no increase in the percentage of salt added has been considered necessary.

It is, we think, desirable in the interests of Irish dairying that the farmers and dairymen of that country should grasp more fully the fact that the absence of cleanliness, cooling, and other necessary precautions conduces to the speedy decomposition of both milk and butter, and that rigid cleanliness alone, or cleanliness coupled with pasteurisation, is essential to counteract this tendency if the milk and butter are expected to remain fresh without the use of preservatives.

In connection, however, with the subject of pasteurisation, it might be well incidentally to point out the relation which pasteurisation bears to the use of preservatives.

*A priori* it might be assumed that the difference between them was merely one of degree, and concerning this, we made it our duty to elicit special information. From this it appeared that milk collected under dirty conditions, or which was for other reasons partially decomposed, cannot, even if subsequently pasteurised, be used for the production of the best butter. From this it follows that the success of pasteurisation as a method in the maintenance of high-class butter depends upon precedent dairy cleanliness.

Although the facts ascertained by us as a result of our inspection have gone far to convince us that there is no sufficient reason, in so far as the dairying industry is concerned, why preservatives should continue to be used in the preparation of Irish butter, we wish to express our opinion that any provision aimed at prohibiting the use of such preservatives should allow a sufficient interval to elapse before it is brought into active operation. We think that if such prohibition were operative forthwith a grave injustice might be done to a large number of persons. We would therefore suggest, that is if the use of preservatives is thought by the Committee to be unde-

sirable, that a reasonable provision would be to prohibit the use of such preservatives in milk and butter from, say, October 30th, 1903. This would allow a considerable interval for the industry to adapt itself to the new condition of affairs; and we cannot refrain from the expression of opinion that such adaptation might be attended with no small benefit to the Irish dairying industry. It is not part of our functions to enumerate the several methods by which the necessary improvements may be brought about, but we may perhaps be allowed to put on record the fact that we heard much during our tour of inspection of the advisability of organising an adequate staff of specially Government inspectors who would be able to aid the dairymen by advice and assistance, and would also be possessed of powers sufficient to enable them to deal with offences against cleanliness.

We would repeat that there are already indications of no uncertain nature pointing to the conclusion that improvement is setting in, and we would add that a prospective prohibition of preservatives such as that of which we have spoken would be likely to facilitate in a material degree the better conception of cleanliness to which we have made reference.

#### ADDENDUM.

LEAFLET of the Irish Agricultural Organisation Society.  
—Creamery Management.

#### Rules for Milk Suppliers.

The superiority of the creamery system over the old methods of butter making being now universally admitted, it is of the greatest importance that everything connected with the creamery and its products be perfectly clean.

In these days of keen competition from all quarters, it is only the very finest butter, of uniform quality, which can realise the best market price. The quality of the butter produced in the creamery mainly depends on the quality and condition of the milk from which it is made; therefore none but perfectly pure and sweet milk, free from any taint whatsoever, should be sent to the creamery. In butter making, nothing but the very finest quality can now be expected to pay dairy farmers, and, in order to produce butter of the best quality, the following simple, yet all-important rules, must be strictly observed:—

#### 1.—Clean the Cows.

See that the cows' udders are thoroughly rubbed or brushed free from all dirt, and that the milker's hands are perfectly clean before milking. The filthy practice of dipping the fingers in the milk before milking must be discontinued. Groom the cow daily. If the hair about the udder is long, and not easily kept clean, it should be clipped.

#### 2.—Clean the Vessels.

The milk pails and cans or churns must be scrupulously clean; first rinse them in warm water, then clean inside and out with a brush and hot water, using some soda if necessary, and afterwards scald them with boiling water and leave them exposed to the air, in a clean place. Use clean water. All milk utensils should be of metal, and have all joints smoothly soldered. Do not allow them to get rusty. Cans should have the separated milk emptied out of them as soon as they get back to the farm, and be cleaned. After cleaning, keep utensils uncovered, in pure air and sun if possible, until wanted for use. After delivering new milk, rinse and scald cans at factory steam jets before receiving separated milk.

#### 3.—Clean the Cow-Houses.

The cow-houses must be kept perfectly clean, and free from injurious smells; they should be regularly swept, to prevent decaying matter from accumulating. Slaked lime should be frequently sprinkled on the floor, and brushed over it. Dairy cows, when stalled, should be kept in a building or room apart from other animals. The byre should be well ventilated, lighted, and drained; the floor should be paved, and the walls should be free from chinks or crevices. Never use musty or dirty litter. Do not allow any strong smelling materials in the byre for any length of time; remove the manure outside to as great a distance as practicable. Whitewash the byre at least twice a year. Use no dry, dusty food

just previous to milking; if fodder is dusty sprinkle it before it is fed. Clean and thoroughly air the byre at least an hour and a half before milking. Cows should always be milked in a perfectly clean place, where no bad odours can contaminate the milk, as it readily absorbs bad smells.

#### 4.—Give Clean and Wholesome Food.

All feeding stuffs which impart their flavour to milk (such as turnips), should be given only after milking, to avoid tainting the milk as far as possible. Where cabbage is fed to cows, all decayed leaves should be carefully removed. Cows should never be allowed to drink impure or stagnant water, but should have a plentiful supply of pure running water. Dirty water is not only injurious to milk, but also to the health of the cow herself. A lump of rock salt should also be provided for the cows to lick. Feed liberally, and use only fresh, palatable foods; under no circumstances should decomposed or mouldy fodder be given. Feed your cows generously in the winter, and the return they will give you in summer will astonish you.

#### 5.—Attend to your Cows' Health and Comfort.

Remove from the herd at once any animal suspected of being in bad health, and reject her milk.

Do not urge cows faster than a comfortable walk when on their way to milking or feeding.

Do not allow the cows to be excited by dogs or hard driving, abuse, or unnecessary disturbance; do not leave them exposed to rain, cold, intense heat, or storms; under no circumstances allow cows to be struck with sticks or stones.

#### 6.—Milking.

Milk quickly, quietly, cleanly, and thoroughly. Milk at the same hour every morning and evening.

Reject the first few strains from each teat; this milk is poor and of little value, and it may spoil the rest.

If any milk appears stringy, tinged with blood, or in any way unnatural, it should be rejected.

#### 7.—How to Treat Dirt.

If by any accident a pail full or partly full of milk becomes dirty, do not try to remedy it by straining, but reject all the milk and rinse the pail thoroughly before using again.

#### 8.—Do your Cows Pay for their Food?

Weigh and record the weight of the milk given by each cow, and take a sample, morning and evening, for testing once a week. Get the creamery manager to test these samples of each cow's milk for you. Some cows are heavy milkers and small butter producers, and *vice versa*. A gallon of milk weighs ten and a third pounds.

#### 9.—How to Treat the Milk.

The churn to receive the milk must be kept in a clean place, and all milk should be carefully strained into it through a fine strainer or clean muslin.

Stir and cool the milk as soon as strained, or get a small aerator and cooler combined. Cool as low as possible.

Never close a can containing warm milk which has not been aerated.

If a cover of the can is left off, a piece of muslin should be laid over it to keep out flies, dust, etc.

If milk is to be kept for any time the cans should be placed in fresh cold water in a clean, dry, and cold room, and should be stirred often enough to prevent a thick layer of cream forming.

Keep the night's milk under shelter to prevent the rain getting in. In warm weather put the cans in a tank of cold water.

Where possible, send milk twice daily to the creamery, and if this cannot be done, send the night's and morning's milk in separate churns. On no account should the hot morning's milk be mixed with the night's milk, but the night's should be cooled immediately after milking, and kept in a cool, clean place during the night.

No preservative should be added to prevent souring; cleanliness and cold are all that are needed.

When milk is carried a distance, the cans should be full, and carried in a spring cart.

In hot weather cover the cans with a clean, wet blanket.

## Appendix.

## 10.—Prevention of Disease.

In the event of any outbreak of contagious or infectious disease in the household of the supplier, notice must be given at once to the creamery, and the supplying of milk discontinued until all danger of spreading disease through the milk is certified by a medical man to have passed.

## 11.—The Creamery Must Get Good Milk.

None but clean, fresh, and pure milk must be sent to the creamery. The milk from newly calved cows should not be sent for five days after calving, and on no account should the milk from ailing or diseased cows be sent to the creamery.

All milk is received at the creamery on the strict understanding that it is pure new milk, and subject to testing by analysis and other reliable methods of ascertaining butter fats, upon which basis it will be paid for alone, and the test of the society's analyst shall be final.

All possible sources of adulteration should be carefully watched by the supplier, so that all possibility of his employees skimming the milk may be avoided.

## 12.—What the Creamery Must Do.

Insist that all separated milk be heated up to 195° F. at least, and then cooled before delivery.

Insist on all pipes, tanks, etc., in the creamery being kept perfectly clean.

To obtain a pure supply at the creamery, it is absolute, October, 1899.

lutely essential that these simple rules be carefully carried out by every supplier, and it is only by so doing that the very finest butter can be made. One single can of tainted or the least injured milk is capable of contaminating and injuring the whole supply with which it comes in contact, and for this reason the creamery manager is obliged, in every such case, to refuse tainted milks.

Similar regulations to these are carefully observed by the farmers of other countries which are competing so keenly and successfully with us, so it becomes necessary that we must do the same, or yield to their competition. It is the interest and should be the duty of every milk supplier to a co-operative creamery, not only to send in pure milk himself, but also to see that his neighbours do likewise. There is no excuse for dirt in dairy farming. It can be so easily avoided, and it is such an expensive luxury.

Where any milk supplier is careless or criminal enough to neglect the observance of the foregoing rules, the whole force of the organised public opinion of the members of his society should be brought to bear upon him until he either mends his ways or is pointed to as the one hopelessly dirty member of the community.

NOTE.—This leaflet is one of a series issued by the Irish Agricultural Organisation Society, Limited, 22, Lincoln Place, Dublin, whose object is to promote combination among Irish farmers wherever and whenever the condition of their industry can be improved thereby. Full particulars on application to the secretary.

## APPENDIX NO. V.

Handed in by Professor Tunnicliffe.

REPORT UPON VISITS TO TWO PRESERVED VEGETABLE AND FRUIT FACTORIES, TOGETHER WITH CERTAIN EXPERIMENTS UPON THE EFFECT OF VARYING THE AMOUNT OF COPPER USED IN THE PRESERVING PROCESS UPON THE ULTIMATE GREENNESS OF THE PRESERVED PEAS.

## I.—Visit to Factory A.

At this factory the following method of preserving peas is followed:—

The peas are boiled in large copper cauldrons, each cauldron dealing at one time with a bushel of peas, approximately 21·8 kilos. The cauldrons are kept perfectly clean, and immediately before a "boil" takes place 2lbs. of salt are placed in each cauldron, which is then filled with water approximately at the boil; the salt is dissolved, and in a few seconds the ensuing salt solution comes up to the boil in the cauldron; 28 grammes of copper sulphate are then added, and the boiling solution well stirred up till it is dissolved. A large copper cullender holding the bushel of peas is then lowered into the boiling copper sulphate and sodium chloride solution. The solution has free access to the peas in the cullender or basket, and these are from time to time stirred with a wooden spoon. The time during which the peas are allowed in this way to boil varies slightly, but the generally recognised time was two and a half minutes. The cook feels the peas from time to time, and determines by their relative softness or hardness whether they are done or not. If they are boiled too long they go brown, even when copper has been added; the older the peas the longer it requires boiling in the copper solution to maintain its green colour.

When the peas are done, the basket or cullender is lifted bodily out of the cauldron and placed in running water, by which means the peas contained in it are thoroughly washed.

The copper used in boiling the peas is weighed in a separate room by a female and made up into parcels, each parcel containing, accurately weighed by us, 28 grammes.

The peas after being washed in water are filled into tins or bottles, and syrup is added to them. The composition of the syrup is as follows:

|       |   |   |   |   |                 |
|-------|---|---|---|---|-----------------|
| Sugar | - | - | - | - | 25·4 kilos.     |
| Salt  | - | - | - | - | 12·7 kilos.     |
| Water | - | - | - | - | 1,600·0 litres. |

The tins or bottles are then placed in an autoclave, where they remain about three-quarters of an hour.

Upon being questioned with regard to the quantity of copper necessary, the manager said the amount he used was a minimum. He had tried to use less, but the peas thus treated had always been returned to him as being off colour. He showed us some of these peas, which were certainly brownish. We further asked him whether the difference between peas with the full and a lesser amount of copper, resolved itself simply into one of time during which the green colour was maintained. He replied to this that it was not a matter of time at all, but was a question of fixing the colour entirely or only partially. The peas practically underwent no change in colour after they left the autoclave.

Through the kindness of the manager we were permitted to make the following experiments—

I.—Some peas were preserved without the addition of copper at all, but were otherwise treated exactly similarly to those preserved with copper. Two bottles of these peas were taken away by us, and kept for seven months, under ordinary conditions with regard to light and temperature. They were then opened, and after some had been taken out for analysis, were re-sterilised, and put up for inspection.

The characters of these peas may be described as follows:—

- (a) Taste, good.
- (b) Colour, greenish light brown.
- (c) Analysis\* showed the presence of copper to the extent of two milligrammes of metallic copper per kilo. These peas were not analysed in the fresh state, but as the amount of copper in them was in excess of that

\* All the analyses refer to the simply strained peas. The liquor was on many occasions qualitatively, on some occasions quantitatively tested for copper.

usually found in fresh peas, it was to be assumed that some of this copper was derived from the copper utensils used in the preserving process.

II.—We preserved some peas in a manner exactly similar to that described above, except that we added 14 grammes of copper sulphate to 21·8 kilos, or just half the quantity generally used. Six months afterwards these peas were opened and treated as described under experiment I. The peas were pale green in colour, here and there brownish, and were found to contain 44 milligrammes of copper per kilo.

III.—In the third instance we preserved some peas exactly as they were usually preserved at this factory, viz., with 23 grammes of copper sulphate per 21·8 kilos of peas.

These last peas six months later were dark green in colour, and were found to contain 90 milligrammes of copper per kilo.

At the second factory we visited the method adopted was somewhat different. At this factory a "boil" of peas consisted of 140lbs. by weight. The peas were boiled in large copper vessels. The copper vessel was first filled with, approximately, three gallons of cold water, and then one ounce of sulphate of copper was added, when this had dissolved, the 140lbs of peas were added, the water then brought to the boil, and kept at the boil for from three to ten minutes, according to the size of the pea, the large peas requiring longer boiling than the small ones. After boiling, the peas were emptied out into a copper cullender, were well syringed with water, and were subsequently filled into bottles only. Syrup was added, consisting of a 1·5 per cent. solution of common salt. The bottles containing the peas were then placed in an autoclave, the stoppers being closed at about 80° C. They remained in the autoclave for about three hours.

The manager at this factory made the same reply to our inquiry concerning the relation between the amount of copper and the time for which the green colour was preserved as the manager of the first factory we visited.

Four grades of peas were used for preserving at this factory. Large, medium, small, and extra small, they are all the same pea, the difference being merely one of size. They are sorted by a machine mesh.

These manufacturers are quite persuaded of the necessity for copper if preserved green peas are to be supplied. They have tried various other green pigments, derived from chlorophyll, but have found none to succeed. They employed for some time a trained chemist. While he was with them he made some experiments upon the fate in the body of the copper ingested with the preserved peas. His results showed that the greater part of it was excreted with the faeces. He also made some estimations of copper in the copper sulphate solution before and after the peas had been boiled in it. His results showed that about half the copper was taken up by the peas, but this varied somewhat with the kind of peas, small peas taking up *ceteris paribus*, more copper, than large peas, weight for weight. The amount of copper taken up was also proportional to the time of boiling. The increased amount of copper taken up per unit weight by small peas as compared to large ones is probably due to the excess of surface offered by small peas per unit weight.

Through the kindness of the manager we were able to make the following experiments:—

I.—We first boiled 15·9 kilos (35lbs.) of the fresh morning's peas in three gallons of water for ten minutes. The peas thus boiled were put up into bottles in the usual way and sterilised in the autoclave. They were kept under ordinary conditions for six months, and were then examined. They were perfectly good, but their colour was greenish brown. Upon analysis they were found to contain 1·2 milligrammes of copper per kilo peas.

II.—We next boiled 15·9 kilos in exactly the same way, except that we added two grammes of copper to the water. The peas were subsequently treated exactly as described under No. 1, and at the end of six months were examined. Their taste was good, but their colour

was practically identical with that of No. I. Upon analysis they were found to contain 18·7 milligrammes of copper pro kilo.

III. We next boiled 15·9 kilos. of peas in the same manner, adding 4 grammes of copper sulphate to the water.—The peas were subsequently treated in the usual manner, and after six months were examined. Their taste was good. Their colour was distinctly green, but was of a yellowish tinge. Upon analysis they were found to contain 38 milligrammes of copper pro kilo.

IV. Our fourth experiment in this connection consisted in boiling the same weight of peas as above in water containing 8 grammes of copper sulphate. These peas after sterilisation, etc., were kept for six months under ordinary conditions, and at the end of that time were found to have a good taste and to be of a full green colour. Upon analysis they were found to contain 74 milligrammes of copper pro kilo.

These experiments seem to show that the quantity of copper taken up by the peas is proportional to the strength of the copper sulphate solution in which they are boiled, when the time remains constant. Thus it would seem to be perfectly consistent, were any standard required, to use the amount of copper per unit weight of peas as such a standard, as this can be varied, at any rate within wide limits, by the preserver at will.

It seems further evident from these results, although they are few in number, and certainly should be amplified, that 50 milligrammes of metallic copper per kilo. is sufficient to ensure the permanency in preserved peas of a quite adequate greenness. Our experience in this regard is not in accord with that of many early observers, both German and French, who regard 0·018 copper pro kilo. as being sufficient to give a lasting green colour to the preserved peas. In our hands peas preserved with this quantity do not practically differ at all from purely natural peas. On the other hand, these experiments show that the quantity sanctioned at present by law in France and Italy—viz., 100 milligrammes pro kilo—is greatly in excess of that used, at any rate by English manufacturers. It may be that these discrepancies—absolutely small, but relatively great as they are—are due to the fact that we worked with different kinds of peas to those used for preserving in France, Italy, and Germany. The general statement that peas preserved with too much copper become bluish-green we should certainly confirm.

We thought it would be interesting in this connection to buy in the open market the following samples of preserved peas:—

V. A sample prepared in France for an English firm, and sold in this country.

These peas were bluish-green in colour, or perhaps to speak more correctly, after twice being sterilised, they possessed the colour of a dark green natural pea, if anything rather erring on the bluish-green side.

They contained 110 milligrammes of copper per kilo.

VI. A sample of peas bought in the open market in Nürnberg in Bavaria. The peas were prepared in Germany, and are similar in nature to those constantly used by the individual who bought the sample.

These are small peas, lightish green, but distinctly green in colour, and were found to contain 73 milligrammes of copper pro kilo.

VII. As there is a law prohibiting the use of copper in Germany, we thought it would be interesting to analyse another sample of German preserved peas. This last sample was prepared in Strasburg and bought in the open market in Germany. The colour of these peas was almost identical with that of sample V. By analysis they were found to contain 104 milligrammes of copper pro kilo.

The results obtained from the foreign samples are interesting in that they seem to point to the fact that considerable difficulty attends, if not actual legislation upon this subject, at least the effectual, or at any rate the successful, enforcement of it.

## Appendix.

## APPENDIX NO. VI.

## EXPERIMENTS UPON THE EFFECT OF BORACIC ACID AND FORMALDEHYDE UPON THE LIVE WEIGHT, GROWTH, AND FOOD ASSIMILATION OF YOUNG SUCKING PIGS,

by

A. D. HALL, Esq., *Principal of the South Eastern Agricultural College, Wye*, and H. S. HAMMOND,

in collaboration with

Professor F. W. TUNNICLIFFE, M.D.

THE experiments described below were undertaken to ascertain if small continual doses of food preservatives like boracic acid and formalin had any effect upon the live weight, growth, and food assimilation of young animals. Whatever may be the general effect of food preservatives upon health, it is obvious that the question is most critical in regard to children; not only is their diet largely or exclusively formed of milk, the article most generally treated with preservatives, but the digestion of the young is particularly liable to disturbances that often affect general health and growth. For the purposes of experiment young pigs were selected; an omnivorous feeder with a short digestive tract, the pig is more akin to man than is any other domestic animal; and what is more important, the young pig grows with extreme rapidity, and is very susceptible to adverse conditions, thus forming a reacting medium of considerable sensitiveness.

The method of experimenting was as follows:—A number of young pigs were kept under observation, and occasionally weighed until it could be seen that certain of them were growing steadily; several pairs of approximately equal weight and condition were then picked out and put on a uniform diet. When we were satisfied that they had settled down to the new conditions, one pig out of each pair received with his food the prescribed dose of boric acid or formalin, which at first bore about the same proportion to the food as exists in the preserved foods met with in commerce. The two sets of pigs receiving otherwise equal amounts of the same food, were kept under observation and weighed at regular intervals, the trials lasting until the pigs had very considerably increased in weight. The food used was meal, made from barley, oats, or wheat, made into a thin paste with water, to this the measured quantity of boric acid or formalin solution was added immediately before feeding.

I.—*Experiments with Boracic Acid.*

Four pairs of pigs, as closely matched as possible, were picked out, all being of the same breed, a Berkshire-Middle White cross. The pigs were about two months old when the observation began. Each pig occupied a separate pen, they were fed as nearly as possible to their maximum capacity, the amounts being adjusted from time to time, but the two pigs which were initially matched as a pair always received exactly the same amount of the same food. The food was varied a little during the trial, in addition to the meal each pig received daily a small quantity of green lucerne or vetches; the whole of the pigs thrived under the treatment so much so that they were ready for market when the experiment ended. The pigs weighed from 30 to 40 lb. to begin with, and increased to from 70 to 90 lb. in the sixty-four days the experiment lasted. The daily ration was 2 to 4 lb. of meal per pig; the daily dose of boracic acid began at 2 grammes, but was gradually increased to 2·4 grammes per pig, a concentration of approximately 1 in 800 of total food.

The actual results obtained are given in Table I. Figure I. shows the successive live weights expressed in curves, the continuous lines representing the weights of the pigs receiving boracic acid, the dotted lines those of the control pigs. The thickened vertical lines represent the dates on which the dose of boracic acid was increased.

It is clear that the differences between the individual curves in each pair are small, and probably within the limits of experimental error, and this is still more probable when the results are combined. In drawing up mean results we have thought it well to cast out No. 2. She was noticed to be "scouring" (diarrhoea) on July 12th, the day before the dose of boracic acid was increased, and though she recovered, the slight loss of weight that ensued was never made up. Casting out No. 2 involves casting out No. 6, the corresponding unit in the pair, so that we have to average the successive weights of 1, 3, 4, and of 5, 8, 7. The effect of this rejection of No. 2 and No. 6 is, however, barely appreciable in the final result. Figure II. is a smoothed growth curve, on which the average weight of 1, 3, 4, receiving boracic acid, are represented by X, and the average weights of 5, 8, 7, without boracic acid, by O. It is obvious that the experimental error must be greater than the differences between the two lots, and that the doses of boracic acid have been without effect upon the rate of growth of the pigs which received them.

*Examination of Faeces.*

During the last twenty days of the experiment recorded above, the faeces of pigs 1 and 5 were systematically collected and preserved. Each pig was confined in a trough of tinned iron, arranged that the urine would readily run off with little or no contact with the faeces, which were collected twice a day. The faeces were to a certain extent contaminated with urine. Each day's faeces were weighed, mixed with 5 grammes of oxalic acid, and carefully dried; when approximately dry each sample was pounded up and well mixed with the faeces of the two following days to make a mixed sample (three-day unit). Six of these three-day samples were obtained from each pig—three when the daily dose of boracic acid was 1·2 gramme, and three after it had been doubled—the sample being rejected that was taken on the day of the change. It was originally intended to analyse the three-day samples separately, but by the time they were ready it had become clear that the boracic acid had been without effect on the live weight of the pigs, hence, to save labour, aliquots were taken from each, and mixed to form samples representing two nine-day periods, before and after the doubling of the dose.

During the twenty days in question the respective pigs received no green food. An aliquot portion of the meal they had each day was preserved so that at the end a mixed sample for analysis, representing the food of the whole period was obtained. The details are given in Tables II. and IIA. The general result is to show that the faeces

contained about half as much fat as the food consumed during the period, the assimilation of fat being apparently more complete in the second than in the first period, as would be expected from the fact that the body weights of the pigs were increasing steadily without any sensible increase in their daily rations.

The difference in the amounts of fat in the faeces of Pigs 1 and 5—i.e., in the control and experimental pig—is so small, that it is covered by errors of experiment, and from this it must be inferred that in this case boracic acid exerted no inhibitory influence upon the assimilation of fat. Less trust can be placed in the results as regards nitrogen, since we were unable to completely eliminate the error introduced by the partial admixture of urine with the faeces. Still there is a distinct agreement in the gross weight of nitrogen (which amounts to about a quarter of the nitrogen of the food) in the faeces of the two pigs. The proportion of fibre in the two lots of faeces is again in as close agreement as can be expected, taking in regard the possible experimental errors. The analytical figures obtained from the faeces and the fat content of the food relating to Pigs 1 and 5 are given in Table IIa.

It is interesting to note that each pig in the two periods plus the two days of interval increased in live weight by about 5 kilos; about 63 % of this increase in weight consists of fat (Lawes and Gilbert. Phil. Trans., 1859), and as only about 690 grammes of fat were consumed in the food and 290 were recovered in the faeces, each pig must have made about 2.75 kilos of fat out of carbohydrate and proteid during the period of experiment. The amount of digested proteid was only about 2.35 kilos, which, if we assume Henneberg's ratio, would yield 1.21 kilos of fat; we thus see what a potent fat-making machine a young pig is. Speaking generally, the analyses made of the faeces of the two pigs under experiment goes to confirm the results of the live weight determinations, and to establish the conclusion that boracic acid was without sensible influence upon the digestion of the young pigs receiving it.

## II.—Experiments with Formalin.

The trials with formalin were conducted on the same lines as those described in the experiment with boracic acid. Six pigs were chosen and kept under observation till it was seen their rate of growth was steady, then the selected ones were matched in three pairs. The pigs in each pair always received equal weights of the same food, but one received a dose of formalin with every meal, suitably diluted, and mixed with the meal and water.

The formalin used was the ordinary commercial (Schering's) 40 per cent. solution of formic aldehyde, and the dose was 2 cc. formalin per pig per diem, increased later to 4 cc. per pig per diem (= 1.6 gramme formaldehyde). As regards the food, this amounted to a concentration of 1 in 730 (minimum with large pig), and 1 in 185 (maximum with small pig).

We were not able to match the pigs so closely in this as in the preceding experiment with boracic acid. Each of the three receiving formalin was a few pounds heavier than the corresponding member of the pair, with normal food, but the differences were not so great as to alter the character of the growth curves. The experiment lasted for seven weeks, during which time the weight of the pigs increased by about 60%, no difference was noted in the state of health of the two lots.

The successive weekly weighings are given in Table III., the food in Table IV.; Figure III. shows the individual growth curves; Figure IV. the mean growth curves, where the whole line represents the successive mean weights of the pigs receiving formalin, and the dotted line the corresponding values for the pigs on normal food.

An examination of the curves shows that the growth of each pig was regular, and that there is no difference between the growth of those receiving formalin and those without, which would not be covered by the experimental error. During the last twenty days of the experiment the pigs 1 and 4 were confined in metal troughs, as described before; a daily collection of the faeces was made, and the faeces dried, but the negative results that had been obtained throughout made it seem unnecessary to proceed to a further examination of the material thus accumulated.

## General Conclusions.

The experiments conducted with boracic acid showed a negative result attending the administration of this substance, and a combinative examination of the faeces of a boracised and normal pig showed no sensible difference in the amounts of fat, nitrogen, and fibre digested in the two cases.

Formalin gave similar results; the administration of formalin did not materially alter the rate of growth.

Our experiments would show that the digestion of young, rapidly growing pigs, as reflected in their general health and increase in live weight, is not sensibly affected by the regular administration over a long period, of doses of boracic acid and formalin in much larger proportions than they are usually employed for the preservation of food.

## NOTES.

*Boracic Acid Experiments.*

Pigs Nos. 1, 2, 3, and 4 had boracic acid; Nos. 5, 6, 7, 8 had no boracic acid, but the same weight of food—viz., Nos. 1 and 5; 2 and 6; 3 and 8; 4 and 7.

Each pig had the same amount of green food per day, except during the period of faeces collection from Nos. 1 and 5, when these two had no green food.

TABLE IIA.—BORACIC ACID. EXAMINATION OF FÆCES.

## FIRST PERIOD OF NINE DAYS.

Boracic Acid dose = 1·2 gramme per diem to Pig 1.  
None . . . . . to Pig 5.

|                                                              | Pig 1.         | Pig 5.         |
|--------------------------------------------------------------|----------------|----------------|
| Weight of Fæces (wet) . . . . .                              | 7,252 grammes. | 8,967 grammes. |
| Weight of Fæces (dry) . . . . .                              | 2,331 "        | 2,552 "        |
| Percentage of Crude Fat in dry Fæces (mean values) . . . . . | 6·27           | 6·215          |
| Percentage of Nitrogen in dry Fæces (mean values) . . . . .  | 2·635          | 2·605          |
| Percentage of Fibre in dry Fæces (mean values) . . . . .     | 22·62          | 20·94          |
| Weight of Fat in Fæces . . . . .                             | 146·2 grammes. | 158·6 grammes. |
| Weight of Nitrogen in Fæces . . . . .                        | 61·4 "         | 66·5 "         |
| Weight of Fibre in Fæces . . . . .                           | 527·3 "        | 534·5 "        |

## SECOND PERIOD OF NINE DAYS.

Boracic Acid dose = 2·4 grammes per diem to Pig 1.

|                                                              | Pig 1.         | Pig 5.         |
|--------------------------------------------------------------|----------------|----------------|
| Weight of Fæces (wet) . . . . .                              | 7,832 grammes. | 8,261 grammes. |
| Weight of Fæces (dry) . . . . .                              | 2,547 "        | 2,530·5 "      |
| Percentage of Crude Fat in dry Fæces (mean values) . . . . . | 5·00           | 5·05           |
| Percentage of Nitrogen in dry Fæces (mean values) . . . . .  | 2·84           | 2·755          |
| Percentage of Fibre in dry Fæces (mean values) . . . . .     | 19·7           | 20·8           |
| Weight of Fat in Fæces . . . . .                             | 128 grammes.   | 125 grammes.   |
| Weight of Nitrogen in Fæces . . . . .                        | 72·3 "         | 69·7 "         |
| Weight of Fibre in Fæces . . . . .                           | 501·3 "        | 526·2 "        |

The food in the first period amounted to 14,970 grammes ; in the second period to 15,210 grammes.

Handed in by Professor TUNNICLIFFE, being a

REPORT UPON CERTAIN EXPERIMENTS MADE UPON THE EXTENT TO WHICH THE COPPER  
INGESTED WITH ARTIFICIALLY-COPPERED PEAS IS ABSORBED AND RETAINED BY THE  
HUMAN BODY.

## Appendix.

The method best calculated to elucidate this problem was to give to a child a known quantity of copper in preserved peas, the greenness of which had been fixed by means of copper on the commercial scale, and to estimate the copper in the excreta voided after their ingestion. Since, however, copper is normally present in our food and our excreta, it was necessary to give a uniform diet throughout the observation, and to estimate what may be termed the normal copper of the faeces.

As the absolute quantity of copper in the substances under consideration, viz., preserved peas, is very small, in order to obtain definite analytical results it was desirable for the child to eat as large a quantity of peas as she conveniently could at one meal. The peas were given instead of her ordinary mid-day meat. That they might replace this accurately from the dietetic standpoint, it was necessary for the amount of peas consumed to be such that their nitrogen was at least equal to that of the meat.

Following this method of reasoning, we fixed the quantity of peas to be ingested at 200 grammes, and this amount the child ate very willingly. As the change from a meat mid-day meal to an equal amount of nitrogen in the form of peas is perhaps somewhat acute, and might vitiate the results of the observation, we thought it advisable to control the results with commercially-coppered peas, by giving the child first the same weight of fresh peas. We did this to eliminate any influence of the peas, *quâ* peas, upon the intestine. This period, which we may term the "fresh pea period," lasting two days, and during which the child ingested 200 grammes of analysed fresh peas per diem, was followed by the "preserved pea period," in which an identical amount of commercially-preserved peas, previously analysed, was consumed.

Since, from the work of many observers, it is established that the copper in properly-preserved peas is present in the form of a phyllocyanate and albuminate, or in an insoluble and in what is known as a "masked" form, it was of interest to ascertain to what extent the absorption of this form of copper differed from that of copper in the form of an ordinary soluble salt. In order to decide this, we added a fourth period to our observation, in which the child took an equivalent quantity of copper, with fresh natural peas, the copper being added as sulphate to the peas after they were cooked and just before they were eaten. Subsequently to this, we allowed the child to return to its weighed and analysed normal diet, but continued for some time to estimate the copper in the urine and faeces; this period constituting the "after period."

We have thought it best to express the results of our observations in the following table, from which also the lengths of the respective periods may be seen\* :—

TABLE showing the relation between the Ingestion and Excretion of Copper during the various periods (expressed in Mg. per diem.)

|                                          | Mg. Cu excreted in |        | Total Excretion. | Total Ingestion with Peas. | Mg. Cu retained. | Per cent. of Cu excreted in Faeces. |
|------------------------------------------|--------------------|--------|------------------|----------------------------|------------------|-------------------------------------|
|                                          | Faeces.            | Urine. |                  |                            |                  |                                     |
| Fore period of eight days.               | 0.29               | -      | 0.29             | -                          | -                | -                                   |
| Fresh pea period of two days.            | 0.72               | Trace. | 0.72             | 0.35                       | -                | -                                   |
| Preserved pea period of two days.        | 10.79              | 0.03   | 10.82            | 14.00                      | 3.18             | 77%                                 |
| Freshly coppered pea period of two days. | 7.45               | 0.03   | 7.48             | 22.06                      | 14.59            | 34%                                 |
| 1. After period of eight days.           | 1.42               | 0.08   | 1.48             | -                          | -                | -                                   |
| 2. After period of four days.            | 0.57               | 0.08   | 0.65             | -                          | -                | -                                   |
| 3. After period of six days.             | 0.35               | -      | -                | -                          | -                | -                                   |

From this table it will be seen that directly after the ingestion of the coppered peas, the amount of copper voided by the faeces underwent a very marked increase. If during the whole of the coppered pea period we subtract the amount of copper in the faeces from that taken by the mouth with the peas, we shall find that 77 per cent. of the copper so taken was at once voided. This copper can, for all practical purposes, be regarded as never having entered the blood. The absolute quantity of the copper remaining is small. It is probably stored up in the liver and excreted slowly with the urine and faeces.\*

In striking contrast to the rapid elimination of copper when taken in the form of "phyllocyanate" is the behaviour of the ordinary soluble salts, for instance the sulphate, when they are ingested with the food. In our observation we probably had to some extent a mixed result, in that the copper of the sulphate, since the latter was well mixed with the peas, after they had been cooked in butter, entered, at any rate in part, into combination with oleic acid and the organic substances in the peas, so that what was actually ingested was oleate of copper, some organic copper compound, and copper sulphate. It will be seen from the table that although a much larger quantity of copper was administered in this case, only a much smaller quantity of it was directly voided with the faeces. If we subtract the quantity of copper present in the faeces from the quantity ingested, we arrive at the result that only 33 per cent. of the copper administered in this way was immediately excreted, and from this it follows that 67 per cent. was retained in the body. There is distinct evidence, as will also be seen from the table, that this copper is slowly excreted by the urine and faeces, more especially by the former, since, at the end of our observation, although the copper in the faeces was approximately normal, the amount excreted by the urine was still continuing to rise.

GENERAL CONCLUSION.—From our research, we regard the conclusion justified that copper, when ingested in the form in which it occurs in carefully-preserved peas, is for the most part voided directly with the faeces, and differs, in so far as concerns its absorption and retention by the human body, from the ordinary salts of copper.

\*The copper, however, thus excreted with the faeces must be distinguished from the copper excreted with the faeces directly after ingestion, for whereas the latter never entered the blood, the former was excreted from the blood by the mucous membrane of the intestine.

\*The faeces belonging to the respective periods were divided from each other by the administration *per os* of charcoal, the copper estimations were made by means of the colorimetric ferricyanide method. For further technical details the reader is referred to a more exhaustive article upon this subject shortly to be published.

## APPENDIX No. VII. (b).

## REPORT ON THE INFLUENCE OF FORMIC ALDEHYDE UPON THE METABOLISM OF CHILDREN; HANDED IN BY PROFESSOR TUNNICLIFFE, BEING A SERIES OF OBSERVATIONS MADE BY HIM IN COLLABORATION WITH DR. OTTO ROSENHEIM.

FORMIC Aldehyde, the simplest possible aldehyde, is a substance possessed of considerable biological and chemical interest. Its biological interest consists in the fact that it has long been regarded as forming the first product of plant assimilation, and has recently been actually demonstrated as such in plants.<sup>1</sup> The ease with which this substance undergoes polymerisation under the influence of simple reagents resulting in the formation of sugars, justifies the assumption that formic aldehyde is an essential link in the building up of complex carbohydrates by plants. In addition to this it has recently been requisitioned as the only possible source of proteid anabolism.<sup>2</sup> Its interest to the physiological chemist is that it combines energetically with proteids and to a less extent with carbohydrates, effecting considerable alteration of their physical and physiological properties. This behaviour seems to be directly antagonistic to the biological rôle ascribed to the substance above. This apparent anomaly of the same substance being both a poison and an essential physiological constituent of living cells is discussed by Loew.<sup>3</sup> It seems to depend upon the fact that what may be termed the biological formic aldehyde is present in small quantities (dilute solutions) and is quickly used up, owing to the ease with which it polymerises or forms innocuous compounds. This last property has an immediate bearing upon the subject of this inquiry in so far as it may serve to explain the results obtained by the administration of small quantities of formic aldehyde to man in his food. It is in this connection that formic aldehyde is of interest to us, and the importance of this subject is, in our opinion, sufficient to justify us in reviewing somewhat exhaustively the results of other observers with regard to the chemical and physiological properties of this substance.

Hofmann<sup>4</sup> discovered formic aldehyde (CH<sub>2</sub>O) in 1869. It is a gas, soluble in water, and obtainable commercially as a 40 % solution which is known as formaline or formol. It has an irritating and pungent odour, and is easily converted into a polymeric solid modification. Its disinfectant action was first pointed out by Loew,<sup>5</sup> and has subsequently engaged the attention of numerous workers, amongst whom may be mentioned Trillat, Aronson, Blum, &c. Their results are mostly of interest to bacteriologists, and are outside the subject of our inquiry. The literature, so far as it concerns us, may be classified as follows:—(i.) Chemical action of formic aldehyde upon proteids; (ii.) Influence of formic aldehyde upon digestions *in vitro*; (iii.) Experiments upon animals.

*Chemical Action of Formic Aldehyde upon Proteids.*

The action of formic aldehyde upon native proteids is in general to render them insoluble. Egg and serum albumen are, however, exceptions. The compounds which formic aldehyde forms with them are soluble and non-coagulable by heat.\* The reaction between formic aldehyde and the proteids is explained by assuming an interaction between the aldehyde and the amido groups of the proteid molecule. There is, however, no proof of this. The insoluble compounds are resistant to the action of the digestive enzymes.† By the action of steam the formic aldehyde is easily split off, the proteids re-formed possessing their original digestibility. (Blum<sup>6</sup>, Bach<sup>7</sup>, Riche<sup>12</sup>, Benedicenti<sup>8</sup>, Beckmann<sup>9</sup>, Mosso and Paoletti<sup>10</sup>, Foulerton<sup>11</sup>.)

According to Lepinois<sup>13</sup>, a 1 % solution of formic aldehyde preserves thyroid glands without affecting either their digestibility or the solubility of the active principle—iodo-thyrin.

The evidence concerning the action of formic aldehyde upon albumoses and peptones is somewhat conflicting.‡

According to Beckmann<sup>14</sup>, gelatine peptone and egg albumin peptone are unaffected by formic aldehyde, whereas hemialbumose is rendered insoluble. Trillat, without giving any experimental data, makes the statement that formic aldehyde renders insoluble all proteid substances not coagulable by heat. This generalisation would, of course, include albumoses and peptones.<sup>15</sup> Lepierre<sup>16</sup> worked on the action of formic aldehyde upon the products of partial peptic digestion isolated by himself—viz., hetero, proto, and deuto albumoses and peptones; also upon commercial peptones, the composition of which he previously examined in the usual manner. According to him there was no action in the cold, and even at 100° C., working with a 14 % formic aldehyde solution, only in some

<sup>17</sup> Bull. Soc. Chim. 1899, t. ix., p. 76.

\* In this regard it may be mentioned that Trillat (Compt. rend. Acad. d. Sc. Paris, 1892, t. cxiv., p. 1279) states that formic aldehyde coagulates albumin as well as blood. Subsequently, Blum (Zeitschr. f. physiol. Chemie, 1896, p. 137) found that formic aldehyde prevents the coagulation by heat of serum and egg albumin in aqueous solution, a fact which has been confirmed by Benedicenti and all later observers.

† Hehner (Analyst, xxii., 1897) said, in a discussion on formic aldehyde, that he had seen the results of certain experiments, which showed that the soluble compound formed by formic aldehyde and egg albumen was digested more easily than egg albumen itself.

‡ Loew (loc. cit.) observed that pure peptone gave no precipitate with formic aldehyde, whilst commercial peptones (Witte) yielded immediately a precipitate in the cold. This he regards as being due to the presence of albumoses (prepeptones).

## Appendix.

cases did precipitation take place; mostly (commercial peptones) no change occurred. From subsequent examination of the resulting solutions, concerning which no details are given, enunciates a theory according to which formic aldehyde causes a progressive regression of the simpler products of proteid digestion back again to the more complicated ones—viz., of peptones to deutero-albumoses, of deutero-albumoses back to proto-albumoses, which finally are precipitated. This observer states further that the compounds formed by formic aldehyde and the proteids are digestible, but less rapidly than the corresponding original proteid, and that these compounds could be reconverted into the original easily digestible proteids by the action of super-heated steam.

*Influence of Formic Aldehyde upon Digestion in Vitro.*

The work done in this connection may be divided into that which concerns itself with the action of the digestive enzymes in the presence of formaldehyde, with their action upon formalised food, and with the effect of formic aldehyde upon the enzymes themselves. The digestions can be considered in this regard *seriatim*.

*Salivary Digestion.*—Rideal and Foulerton<sup>1</sup> estimated the amount of maltose formed from arrow-root starch by saliva alone and in the presence of formic aldehyde in different proportions. Taking the control as 100, they found that ptyaline in the presence of 1 in 100,000 formic aldehyde converted 99·8%, in the presence of 1 in 10,000 89·00%. Foulerton<sup>2</sup> tested the progress of starch conversion in the presence of formic aldehyde, and found that dilute solutions, 1 in 40,000 to 1 in 1,000, had a retarding but not an inhibitory action.

The relative convertibility of previously formalised starch into sugar by means of ptyaline has, so far as we are aware, only been investigated by Bliss and Novy.<sup>3</sup> These observers found that a 1% starch paste, previously kept for five days at 35° C. with formic aldehyde (1 in 100), behaved with ptyaline exactly as fresh starch paste.

The same investigators showed that formic aldehyde, in the strength of 1 in 1,000, exerts very little action upon ptyaline itself, unless the mixture is allowed to stand for several days, or is kept at 35°–40° C. With stronger solutions of formic aldehyde the effect is more marked, the ferment being destroyed by the action of 1 in 1,000 for nine days at 40° C.

*Rennet.*—Pottevin<sup>4</sup> observed that formic aldehyde added to milk retarded its coagulation by rennet, and that rennet itself (*loc. cit.*) was rendered inactive by strong solutions of formic aldehyde.

Bliss and Novy also examined the action of rennet upon formalised milk, and found that milk which had been subjected to the action of formic aldehyde, 1 in 1,500, behaved in this respect very similarly to normal milk (normal milk coagulated in 15 minutes, this formalised milk in 20 minutes). Milk which had been acted upon by formic aldehyde, 1 in 1,500 for 1 hour, behaved identically with normal milk.

Foulerton's<sup>5</sup> experiments with rennet show that formic aldehyde added to milk in the proportion of 1:40,000, whether at the same time as the enzyme or 48 hours before, has practically no influence upon the process of coagulation. With higher proportions up to 1 in 5,000 coagulation was retarded, but not prevented. This was also the case to a more marked degree with solutions of 1 in 1,000. These results with higher proportions do not correspond with those of Bliss and Novy detailed above. The discrepancy in the results of these two observers is probably to be explained by the variations in milks and rennets used. It will be noted that the behaviour of the control milks was not identical (coagulation in 15 mins. Bliss and Novy, and 30 mins. Foulerton).

Halliburton<sup>6</sup> observed that strong solutions of formic aldehyde delayed rennet action, more dilute solutions acted similarly but to a less marked degree. Freudenreich<sup>7</sup> observed that formic aldehyde in the form of vapour had a destructive influence upon rennet, but that in solution in the strength of 1 in 500 it had no appreciable action upon its milk coagulating power.

With regard to the action of formic aldehyde upon the rennet ferment itself Bliss and Novy<sup>8</sup> found that it had no apparent effect upon this ferment, even when present in the proportion of 1 in 50.

*Peptic Digestion.*—Symons<sup>9</sup> found that formic aldehyde did not influence peptic digestion.

According to Mayberry and Goldsmith<sup>10</sup>, when pepsine was allowed to act upon fibrin in the presence of formic aldehyde the amount of fibrin digested diminished with the increasing percentage of formic aldehyde. Taking the control as 100, they found that, when formic aldehyde was present in the proportion of 1:2,000, 97·74% of the fibrin was digested, when present in the proportion 1:1,000 94·34%.<sup>11</sup>

Rideal and Foulerton<sup>12</sup> concluded from carefully executed quantitative experiments that the addition of formic aldehyde immediately before digestion in the proportion of 1:50,000 had no appreciable effect. Their quantitative results were as follows:—When formic aldehyde was added in the proportion of 1:50,000 immediately before digestion, the amount digested in unit time was 97·63%, taking the control as 100.

With regard to *previously formalised* proteid they found that (taking again the control as 100) 91·45% was digested in the case of fresh beefsteak previously formalised for twenty-four hours with 1:100,000, 90·38% when the strength was 1:50,000, 85·25% when formic aldehyde was increased to 1:10,000. From these results they conclude that formic aldehyde has no influence on the digestibility of the food after contact with it for twenty-four hours prior to the action of the enzyme.

These conclusions have been criticised by Hehner<sup>13</sup>, and in a subsequent paper Foulerton<sup>14</sup> modifies them considerably, and infers that in addition to any possible effect which formic aldehyde may have on the action of the enzyme, it also renders food itself less digestible.

Bliss and Novy<sup>15</sup> found that the digestion of fibrin by pepsin, both previously formalised for twenty-four hours preceded normally when the strength of formic aldehyde was 1:2,500, and even when it was increased to 1:100 the fibrin was eventually digested.

Halliburton<sup>16</sup> made a series of experiments on the relative digestibility of fibrin previously treated with formic aldehyde (for from two to three days with 1:100 to 1:2,000). He found that previous formalisation with 1:2,000 for two days delayed gastric digestion twenty minutes, for three days for thirty minutes. Formalisation with a 1% solution did not prevent digestion, the latter becoming complete in twenty-four hours.

Loew<sup>17</sup> was the first to study the action of *formic aldehyde on pepsin* and found that when this enzyme was exposed to strong solutions for one day it lost its activity.

Bliss and Novy<sup>18</sup> subsequently found that pepsin is not affected by a 1% solution of formic aldehyde, even when the mixture has stood for four weeks. Even a 5% solution acting for three weeks has no effect on pepsin. Contrary results by others are explained as being due to an alteration of the fibrin by the aldehyde, before the pepsin could act.

*Pancreatic Digestion.*—Symons<sup>19</sup> found that when formic aldehyde was added to the digestive mixture in the

<sup>19</sup> Loc. cit.

proportion of 1 : 2,000, it had a distinctly retarding influence on pancreatic proteolysis (fibrin), whilst 1 : 300 completely inhibited digestion.

Rideal and Foulerton<sup>1</sup> results showed that when formic aldehyde was added in the proportion of 1 : 50,000 to milk immediately before its artificial digestion with commercial pancreatin 97.0 % of casein were digested, taking the amount digested in the control experiment as 100.

With regard to *previously formalised* milk the same authors found that 94.1 % casein was digested when milk formalised to the extent of 1 : 50,000 was acted upon by commercial pancreatin (taking as before the amount digested in the control as 100).

Bliss and Novy, working with commercial pancreatin and fibrin, found that fibrin previously formalised for twenty-four hours with 1 in 1,000 formic aldehyde was digested much more slowly than fresh fibrin, but that its total digestion did eventually take place. The same observers, working with *fresh pancreatic extract*, found that when fibrin was formalised for twenty-four hours with 1 in 1,000 there was no influence upon its digestibility, whilst when 1 in 500 was used there was a slight retarding influence.

Halliburton<sup>2</sup> studied the effect of previous formalisation upon the digestibility of fibrin by means of commercial pancreatin, and found that whereas the digestion of fresh fibrin was completed in thirty minutes, that of fibrin, previously formalised by an exposure to formic aldehyde solution, 1 in 2,000, for two days, required ninety-five minutes for its completion. In the case of formalisation with stronger solutions no signs of digestion occurred within twenty-four hours.

Loew<sup>3</sup> observed that when a *solution of trypsin* was treated with formic aldehyde a precipitate occurred. The action of formic aldehyde upon the pancreatic enzyme has been carefully studied by Bliss and Novy.<sup>4</sup> They found in the case of commercial pancreatin (Parke Davis) that solutions of formic aldehyde in the strength of from 1 in 1,000 to 1 in 100, acting for twenty-four hours, completely destroyed its proteolytic activity. In the case of freshly-prepared pancreatic extract the influence was not so marked; a strong extract, previously formalised for twenty-four hours with 1 in 1,000, digested formalised fibrin (1 in 1,000) normally. When the ferment solution was previously formalised with 1 in 500 there was a distinct retardation in the case of the *strong extract, and absolute destruction of proteolytic power* in the case of the weak extract.

*Amylolytic Ferment of Pancreas.*—Rideal and Foulerton<sup>5</sup> tested the activity of the amylolytic ferment of two samples of commercial pancreatine in the presence of formic aldehyde. They found that when formic aldehyde was added immediately before digestion, so that it was present in the digestive mixture in the proportion of 1 in 50,000; 91.8 % maltose was produced in the case of Extract No. I., and 84.00 % in the case of Extract No. II. When the formic aldehyde was present in the proportion of 1 in 10,000, 91.5 % and 83.0 % maltose were produced respectively. The amount produced under normal conditions was taken as 100.

Halliburton<sup>7</sup> made a few experiments with regard to starch conversion by means of commercial Liq. Pancreaticus (Benger) in the presence of formic aldehyde, and found that the strongest solution of formic aldehyde caused a retardation of total conversion amounting to five minutes, the weakest a retardation amounting to two minutes. Bliss and Novy<sup>8</sup> made some observations upon the amylolytic power of previously formalised, freshly prepared pancreatic extracts. From their results it follows that formic aldehyde has very little influence upon them. Amylopsin, previously formalised for twenty-four hours with 1 in 1,000, was not affected; even 1 in 500 exerted but little action. Lipase seems unaffected by formic aldehyde (Kastle and Loewenhardt Am. Chem. Journal xxiv. No. 6).

#### Experiments upon Animals.

The symptoms produced by formic aldehyde consist in strong local irritation. The animals become restless, and exhibit clonic convulsions and opisthotonus. They finally pass into a condition of coma, during which the respiration is quick and irregular in rhythm, the cause of death being asphyxia. According to Benedicenti<sup>9</sup>, formic aldehyde is a blood poison, converting hæmoglobin into hæmatin.

The toxicity of formic aldehyde upon higher animals seems to be relatively low, and differs considerably according to the animal.

Trillat<sup>10</sup> gives the lethal dose per kg. body weight for guinea pigs as 0.8 g. when injected *sub cutem*, whilst 0.53 and 0.66 produced no effect: 0.038 g. per kg. guinea-pig injected into a vein was also without result.

Berlitz and Trillat<sup>11</sup> found the toxic dose for dogs (intravenous) to be 0.07 g. pro kg., and for rabbits (intravenous) 0.09 g. pro kg.

Aronson<sup>12</sup> found 0.24 g. per kg. body weight to be lethal for rabbits, and according to Pottevin<sup>13</sup> larger doses than 0.25 g. pro kg. *sub cutem* and 0.03 g. per kg. intravenous are lethal for the same animal. 0.016 g. injected into the veins of rabbits for four days in succession produced no effect.

According to Mosso and Paoletti,<sup>14</sup> 0.32 g. pro kg. proved lethal for dogs, while 0.22 g. produced serious symptoms.

Bruni<sup>15</sup> found that 0.28 g. pro kg. killed a dog, to which the same dose had been administered *per os* the day before.

When administered by the mouth the results obtained are somewhat conflicting.

Blum<sup>16</sup> gave to a rabbit weighing 1,500 g., 0.72 g. formic aldehyde in two doses, in the form of a 1 : 2 % and of 2 : 4 % solution. The animal refused food for a day. He also administered 1.5 cc. of a 40 % formalin solution—that is, 0.6 g. formic aldehyde—to a hare. The hare took its food normally after two days.

U. Mosso and Paoletti<sup>17</sup> gave to a dog 0.04 g. formic aldehyde in the form of a 1 in 250 solution. Vomiting ensued. Subsequently they gave 0.022 g. formic aldehyde in the form of a 1 : 500 solution. No vomiting occurred, but symptoms referable to an action of the drug upon the central nervous system. A dose of 0.011 g. in the same dilution produced no effect.

Bruni<sup>18</sup> found that 0.032 g. of a 1 : 1,000 solution had no effect upon a dog weighing 7.2 kg., and that 0.28 g. formic aldehyde in the form of 1 : 500 solution caused vomiting in a dog weighing 14 kgs. After fifty minutes no further disturbances occurred.

Some experiments have been made with regard to the general effect of doses of formic aldehyde continued for some time upon animals.

Rideal and Foulerton<sup>19</sup> fed cats three months old for a period of several weeks on milk containing formic aldehyde to the extent of 1 in 50,000, 1 in 25,000, and 1 in 20,000, and in two cases noted an increase in weight, while in one case the weight remained constant. They further fed one rabbit in the same way, estimating the amount of nitrogen in the food and the excretions, and found that the animal gained in weight, and that although there was some increase in the excretion of nitrogen, the nitrogen balance remained positive. These observers,

however, give no control experiments. Reviewing these experiments in a later article<sup>1</sup> Foulterton concludes that these observations were not sufficiently numerous to allow of any stress being laid upon them either one way or the other.

Annett published some experiments<sup>2</sup> on young kittens three or four weeks old extending over several weeks. These he fed on milk containing formic aldehyde 1 in 50,000, 1 in 25,000, and 1 in 12,500. Control experiments were made on a smaller number of kittens fed on normal milk. The quantity of milk taken by each kitten is not given, therefore no data are available with regard to the quantity of formic aldehyde consumed by each kitten. These experiments and the conclusions drawn from them have been criticised at length by Liebreich<sup>3</sup> and Rideal,<sup>4</sup> who have pointed out that the results were so irregular\* in comparison to the number of animals experimented upon, that no important conclusions could be drawn from them.

Rideal further pointed out that cows' milk as such is an unsuitable food for kittens of that age, and that six kittens fed on undiluted fresh cows' milk all died. Rideal in the same paper published a series of observations upon kittens five weeks old fed with 70 cc. of cows' milk per diem formalised to the extent of 1 in 5,000 he noticed under these conditions no injurious action but an increase in body weight.

In this connection some experiments have been made by A. D. Hall and H. S. Hammond in collaboration with ourselves at the South Eastern Agriculture College, Wye. These observations will be published fully elsewhere; they showed that the continuous administration for six weeks of from 8 to 1·6 grammes daily of formic aldehyde with a mixed diet had no effect upon the live weight of young sucking pigs. The initial weight of the pigs varied from 25 to 58 lbs., and the quantity of formic aldehyde given amounted to a concentration of from 1 in 185 to 1 in 730 total food.

Concerning the fate of formic aldehyde in the animal body, the results of various observers are not in accord.

Trillat (loc. cit.) found that the guinea-pigs' urine underwent no fermentative change after they had been injected with formic aldehyde. According to Aronson (loc. cit.) the urine of rabbits after the administration of large doses of formic aldehyde has a reducing action upon ammoniacal silver nitrate, and gives Schiff's reaction for aldehydes. Blum (loc. cit.) could not find formic aldehyde in the urine of rabbits after doses of 0·6 g., but obtained traces of formic acid.

Quite recently Filippi and Martoleni<sup>5</sup> have studied the fate of formic aldehyde in the body after injection. The object of the research seemed to be to determine whether the results of Albertoni<sup>6</sup> concerning acetic aldehyde—namely, its complete excretion as such without oxidation—were true for formic aldehyde. They seem unaware of the fact that these results have not been confirmed by Reizhenstein.<sup>7</sup> They quote Perando<sup>8</sup> as having found that formic aldehyde is completely oxidised in the body to formic acid, and call into question his methods. From their own experiments they conclude that formic aldehyde, after its administration in apparently very large doses, could be found in all the organs of the body, the colour reaction upon which they relied being most marked in the intestines, lungs, and kidneys. No mention is made as to its presence in the urine.

Among the compounds of formic aldehyde easily decomposable into the original substance, Pohl<sup>9</sup> has examined

the fate in the body of the sodium sulphite compound  $\left( \begin{array}{c} \text{OH} \\ | \\ \text{HCH} \\ | \\ \text{SO}_3\text{Na} \end{array} \right)$ . After the administration of 5 g. of

this substance to a dog, no aldehyde reaction could be obtained in the urine, but there was a very slight increase in the amount of formic acid normally present. The fate of the ammonium compound of formic aldehyde (Hexamethylenetetramine or urotropin) is discussed by Nicolaier<sup>10</sup> in his original communication. His results have subsequently been confirmed by other observers. Urotropin appears rapidly in neutral or alkaline urines as such, and in acid urines as formic aldehyde.

With regard to the fate of formic aldehyde in the body, the observations of Pohl (loc. cit.) are of interest. He found that the fresh organs of warm-blooded animals, especially the liver, can oxidize formic aldehyde to formic acid. Jacobi<sup>11</sup> isolated a pure ferment from the liver of oxen, possessing very strongly the power of oxidizing aldehydes, especially salicylic aldehyde.

*Action on Man.*—Very little is known concerning the action of formic aldehyde on man, either in therapeutic or poisonous doses. A case of poisoning is recorded by Andes<sup>12</sup> in which a "spoonful" of a 40 % formic aldehyde solution was taken by mistake. Ammonium acetate and an emetic were administered immediately, and complete recovery took place in two days. No general symptoms other than those referable to shock were recorded.

Another case is mentioned in the Medical Press<sup>13</sup>, where a youth took about 2·5 grammes of formic aldehyde in the form of a 4 % solution. Vomiting occurred, and death twenty-nine hours afterwards from heart failure. A post mortem examination showed "that the oesophagus was slightly inflamed, and escharotic changes were visible in the stomach."

Trillat<sup>14</sup> gave 5 grammes of the polymerised solid modification of formic aldehyde to patients, without any poisonous symptoms. Aronson records similar experiences with paraform aldehyde.

The ammonia compound (urotropin) mentioned above is used extensively in medicine.

Quite recently<sup>15</sup> 50 cc. of a 1 in 2,000 solution of formic aldehyde has been injected intravenously as a means of treatment in pulmonary tuberculosis without any symptoms of poisoning occurring. The injections were continued over a considerable time.

## Critical Review of Literature.

In this connection we do not purpose considering formic aldehyde from either a therapeutical, bacteriological or toxicological standpoint, but from the standpoint of its possible use as a food-preservative. This limitation of our point of view brings us at once to a limitation of material and quantity. Material in so far as we have only to consider milk, and quantity in so far as only those experiments are relevant in which formic aldehyde is used in quantities not in excess of those necessary for its action as a preservative. In this regard the strong solutions are at once excluded owing to their taste, and because they are unnecessary.†

\* E.g., he obtained three deaths in the case of the 1 in 50,000 milk, none with the 1 in 55,000, and two with the 1 in 12,500.

† By the assistance of a number of observers we were able to convince ourselves that formic aldehyde in the strength of 1 in 2,000 imparted to milk in the cold a characteristic taste. If the milk were warmed to drinking temperature 1 in 5,000 could be easily detected.

From a careful consideration of the results of various workers we are inclined to accept 1 in 25,000<sup>1</sup> as the maximum quantity which can possibly come in regard in this connection; but, as it will be seen from the context, we took for the purpose of our own experiments a higher proportion (1 in 10,000 and 1 in 5,000).

If we consider the literature, keeping these limitations in mind, the following points are to be emphasised:—

From the experiments made to ascertain the chemical action of formic aldehyde upon the proteids generally, the conclusion may be drawn that compounds of a more or less definite composition are formed, and that the digestibility of these compounds is less than that of the original proteids. All these experiments, however, relate to compounds produced by the action of an excess of formic aldehyde, none being recorded with dilution approximating to that of the above adopted standard. Taking in regard the complex nature of milk and the excess of chemical compounds capable of combining with formic aldehyde in it, in proportion to the very small amount of formic aldehyde added, it does not seem to be justifiable to draw *a priori* conclusions as to the effect of formic aldehyde upon the digestibility of the proteid constituents of milk, from the mere chemical data above.

With regard to the chemical reactions between formic aldehyde and the products of partial or complete proteid digestion, we must bear in mind again that so far as we know these reactions only take place at unphysiological temperatures, and with relatively concentrated solutions of formic aldehyde.\*

If we direct our attention to the digestion experiments *in vitro* with formic aldehyde, we come to the conclusion that, speaking generally, under the conditions of these experiments, formic aldehyde has a retarding effect upon the digestion of food by the various enzymes concerned. In the case of peptic digestion, this effect is less marked (according to some observers there is no effect) than in the case of pancreatic. The general value of these conclusions is, however, in our opinion, somewhat lessened by the following considerations. All experiments have been made with commercial pepsin or trypsin, except the later pancreatic digestions of Bliss and Novy, from which it is manifest that the difference between the digestibility of formalised and fresh proteid is far less marked in the case of fresh trypsin, than in that of commercial. These observers found that, in the case of freshly prepared pancreatic juice, fibrin formalised with 1 in 1,000 formic aldehyde, was as digestible as fresh fibrin. Since we have no experimental data with regard to fresh pepsin, we cannot tell to what extent the activity of this latter might have been affected by formic aldehyde.

No digestion *in vitro* following physiological sequence has been carried out, in no case has the residue of the gastric digestion of a formalised food been subjected to pancreatic digestion. No quantitative experiments, as far as we are aware have been made concerning the most important point under consideration, viz., the gastric digestion of formalised milk.

It has been pointed out by many critics<sup>2</sup> that conclusions from experiments *in vitro* can only be applied, if at all, to living animals with great caution, since the conditions which obtain in the living stomach are much more complicated, and impossible to imitate *in vitro*. To mention one of the more gross objections, we may point out that no attempt is made in digestions *in vitro* to imitate even the mechanical conditions which obtain in the living stomach, which effect both a continuous churning of the food with the digestive juice, and a continuous removal of the products formed. Further, from the purely biological standpoint, according to the interesting experiments of Pawlow,<sup>3</sup> the food seems, by virtue of its relative digestibility, to have an influence upon the nature of the secretion produced by the stomach to digest it. In addition, a possible stimulant action on the part of formaldehyde must not be overlooked, so far as concerns the secretion of the enzymes and their quality, apart from a possible stimulant action upon their activity. That formic aldehyde seems to have a stimulating action upon certain enzymes may be concluded from the experiments of Macfadyen, Morris, and Roland<sup>4</sup> on Buchner's Zymase, and from those of Weigle and Merkel<sup>5</sup> upon diastase, and from those of Kastle and Loewenhardt upon "Lipase."

With regard to the experiments on animals, only those interest us in which the formic aldehyde was given by the mouth. Even in these the formic aldehyde was in no case given with food, but in a free state in water; and when any effect was produced at all, the drug was present in a concentration and in an amount far in excess of that in which it would be given as a preservative in food. So far as concerns the effect of formic aldehyde when given to animals admixed with food for long periods, the results are conflicting, but, on the whole, seem to show that formic aldehyde in moderate doses has little or no influence upon the growth, weight, and general health of even young animals.

It will be seen from the above criticism that, although we are provided with a copious indirect literature, no conclusions, in the absence of direct observations upon man, can be drawn concerning the possible effect upon him of the addition of small doses of formic aldehyde to his food. It was clear to us that the only way to fill this gap in the literature was to make such observations, and the kind of observation best calculated to give exact and definite data for conclusions was, in our opinion, a series of metabolic experiments.

#### *General Arrangement and Method of Experiments.*

Before entering into the details especially relevant to our own observations, it might be well to recapitulate briefly the general principles of metabolic experiments. They consist in the exact estimation of the quantity of food and its various constituents during a given period, and the estimation during the same period of the total excreta and their constituents, chiefly with regard to nitrogen, phosphorus, fat, &c. By this means we get valuable information with regard to the assimilation of these substances by, and their retention in the body. We should like to point out, however, that there is a slight fallacy in this reasoning, in that our knowledge of the origin of faecal nitrogen is somewhat limited. According to Prausnitz<sup>6</sup>, the whole of the nitrogen in the faeces arises, not from the unabsorbed nitrogen of the food, but from intestinal secretion (epithelial cells, &c.). The value of the metabolic method is not to any extent affected by this, in so far as all nitrogen excreted by the faeces must be regarded as lost to the body, and its subtraction from the quantity of nitrogen ingested gives us the quantity of nitrogen retained. It must, however, be observed at once, as has been emphasised by Pawlow<sup>7</sup>, that the results of these experiments give us no absolute information with regard to the actual digestibility of any given food, in so far as we are left by them in complete ignorance of the amount of energy spent by the organism in producing the observed effect. Providing the organism is equal to the occasion, an indigestible food might be as well assimilated and retained as a digestible one; but to produce this result an additional output of energy would be required. If this additional output of energy were relatively small we should probably have no indications with regard to it, but were it relatively large, or, in other words, were the difference in the digestibility of the foods in question great, we should probably find that the body weight, or the general health of the person under observation, would be affected, and this effect would be the more noticeable the longer the period of observation, and the more sensitive the person chosen.

On general principles we thought it advisable to allow our observations to extend over comparatively long periods, and to take what were *a priori* to be regarded as relatively sensitive re-agents—viz., children, both robust and delicate, and to observe minutely during the various periods their general health and behaviour. From

<sup>1</sup> Vide Droop Richmond and Harrison. Analyst, 1900, p. 116. It is further interesting in this connection to observe, assuming Benedict's figures to be correct (loc. cit., p. 243), that milk could fix owing to its 3% of casein in 0.0036% formic aldehyde, whilst 1 in 25,000 formic aldehyde corresponds to 0.004%. There seems to be a relation between the fixing of the formic aldehyde by the casein and its power as a preservative as the time during which this amount will keep milk sweet corresponds approximately to the time required for the proteid to fix all the formic aldehyde.

## Appendix.

another standpoint children had in this connection an additional interest, on account of the fact that milk forms so large a proportion of their diet, and it is to milk that formic aldehyde as a preservative is generally added.

Our observations were made upon three children, two of whom (boys) might be regarded as typically healthy, and were aged 2½ and 5 years, the third child, girl, aged 4 years, was delicate, being convalescent from pneumonia. We shall refer to the children subsequently as A., B. and C respectively. During the whole period the children were under our perpetual observation, and absolute control was kept over all ingesta which were accurately weighed by us, and excreta which were collected in diurnal periods without loss. The general conditions of their life remained constant, they were kept for some time before the "fore period" of the observation began under identical conditions to those obtaining during the observation. They took each day the same amount of exercise, and their habits were in every respect regular. The research was carried out during the months of April and May, and extended in the case of A. and B. over a period of four weeks, in the case of C. over one of three weeks. Each period was subdivided into three—a fore, a middle or formic aldehyde period, and an after period. The relative lengths of these periods will be seen from the tables. The children had a mixed diet. With regard to the quantities of the different food-stuffs, we were guided at first by the work of Camerer<sup>1</sup>. This was subsequently modified to a small extent by our own observations concerning the establishment of nitrogenous equilibrium in which the children were approximately placed before the fore period began. Every article of food was carefully analysed with regard to its percentage composition, and in no case were so called average figures taken.

In order to minimise the amount of analytical work entailed by this method, the three children were supplied from the same stock of foods, which were taken originally in as large a quantity as was consistent with their keeping properties. To this end Pasteurised milk was supplied to us in bottles, each lot of bottles being taken from the same churn<sup>2</sup>. Each lot of meat lasted for about four days; lean beef was usually taken, and the whole stock minced; a sample of this was then analysed.

The following table shows the percentage composition of the foods used:—

TABLE I.—Showing the percentage Composition of Foods.

| —                   | Specific Gravity. | Water % | Fat % | Total % Carbohydrates. | Nitrogen % | Phosphoric Acid % | Ash % |
|---------------------|-------------------|---------|-------|------------------------|------------|-------------------|-------|
| Lactose.            |                   |         |       |                        |            |                   |       |
| Milk I. . . .       | 1·0329            | 86·55   | 4·50  | 4·92                   | 0·49       | 0·29              | 0·69  |
| " II. . . .         | 1·0331            | 86·92   | 3·85  | 4·03                   | 0·58       | 0·28              | 0·70  |

The excreta were collected without loss, in twenty-four-hour periods from 8 a.m. to 8 a.m. and worked up the same day. The faeces were weighed in their normal state each day, small quantities of acid added when necessary, and subsequently evaporated on a water-bath. When dry they were finely powdered, weighed, and analysed. The faeces belonging to each period were separated by means of the administration of powdered charcoal.

*Methods of Analysis.*—All nitrogen estimations were made by Gunning's<sup>3</sup> modification of Kjeldahl's method. It was found advantageous, especially in the analysis of the faeces, to add a few crystals of copper sulphate to the mixture of sulphuric acid and potassium sulphate, as by this means a very rapid and quiet oxidation was obtained. Two methods of phosphorus estimation were used. In food, faeces, and urine the total phosphorus was estimated by Neumann-Keller's method,<sup>4</sup> viz., by oxidation in a Kjeldahl's flask by means of nitric acid and ammonium nitrate, subsequent precipitation with molybdic solution, &c., and weighing as magnesium pyrophosphate. For the estimation of lecithin phosphorus in the ethereal extract of the faeces, the usual process was used (oxidation by means of a mixture of sodium carbonate and nitrate, and subsequent estimation of phosphorus as before). The carbohydrates were estimated gravimetrically as dextrose or lactose, by means of Fehling's solution. The fats, which term includes all the ether soluble substances, were estimated by extraction in Soxhlet's apparatus, after previous treatment with alcohol. According to E. Voit<sup>5</sup> lecithin was estimated by multiplying the phosphorus figure obtained from the filtered ethereal extract of the faeces with the factor 7·27, corresponding to distearyl-lecithin. The uric acid was determined by our own modification of Hopkin's method.<sup>6</sup> The total and ethereal sulphuric acids were estimated according to Baumann's method.<sup>7</sup>

<sup>5</sup> Zeitschr. f. Biologie, xxxvii., p. 555.

<sup>6</sup> Centralbl. f. Physiol., 1897, p. 434. It has been shown by the most recent workers that the initial precipitation of uric acid by means of ammonium chloride is just as reliable as the more complicated method of Salkowski Ludwig when certain conditions are observed. (Ritter, Frodin, Wörner, &c.).

## Observation I.—Child A.

Appendix.

The child was a healthy boy, aged 2½ years, weighed 14·6 kilos, and remained in good health throughout the whole observation. He consumed daily as follows:—200 g. of bread, 550 cc. of milk, 20 g. of butter, 30 g. of meat, 50 g. of apple compote, 10 g. of sugar, 50 cc. of water, 5 g. of toffee. This diet was very well taken and adhered to throughout the experiment. The whole observation extended over twenty-eight days, seven days being taken for a fore period and seven days for an after period, during the intermediate fourteen days formic aldehyde was administered. In the first seven days of this intermediate period formic aldehyde was given in the morning and evening milk in such quantity that it was present in the proportion of 1 in 10,000, the actual quantity given per day was 0·05 g., formic aldehyde in 500 cc. of milk. The formic aldehyde was added to the milk in the morning about 7.30 a.m., 250 cc. of the milk were taken at about 8.30 a.m., and 250 cc. at 5 p.m. It will be seen therefore that we not only gave freshly formalised milk, but milk which had been exposed to the action of formic aldehyde for a considerable time. The whole food per diem weighed approximately 900 g.; it therefore follows that the total food and drink during the first week of the formic aldehyde period was formalised to the extent of 1 in 18,000. During the second formic aldehyde period the dose of formic aldehyde was doubled, viz., 0·10 g. per diem, equal to 1 in 5,000 in milk, and 1 in 9,000 in total food and drink. The increased dose, viz., 0·05 g., was occasionally given with the meal at dinner and occasionally in the milk. The analytical results obtained throughout the observation are recorded in the table on pages 320 and 321.

The results expressed in the table (pages 320 and 321) are graphically represented in the following curves:—

Curve I.

Showing the influence of formic aldehyde upon nitrogen and phosphorus metabolism, &c.

Curve II

Showing the influence of formic aldehyde upon fat assimilation and quantity of faeces and urine.

Appendix.

## Appendix.

Referring to the tables and curves relating to the *first observation*, we will classify our remarks under the following headings:—

*Nitrogen Metabolism.*

In the fore period the daily quantity of nitrogen taken in the food was 6·88 g., of which 0·59 g. was not assimilated, being lost with the faeces, corresponding to 8·58%. The assimilation of nitrogen in the fore period amounted therefore to 91·42%.

With the urine 5·28 g. of nitrogen was excreted, and if this be subtracted from the amount assimilated, we obtain a daily balance of +1·02.

To avoid repetition, we give the results with regard to the nitrogen balance and assimilation during the different periods in tabular form:—

|                             | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|-----------------------------|--------------|--------------------|---------------------|---------------|
| Nitrogen of Food - - - - -  | 6·88         | 6·66               | 6·37                | 7·09          |
| „ „ Urine - - - - -         | 5·28         | 5·15               | 5·22                | 5·15          |
| „ „ Faeces - - - - -        | 0·59         | 0·64               | 0·51                | 0·54          |
| „ Balance - - - - -         | +1·02        | +0·87              | +0·64               | +1·40         |
| „ Assimilation % - - - - -  | 91·41        | 91·22              | 91·99               | 92·38         |
| „ of dry Faeces % - - - - - | 6·1          | 5·9                | 5·9                 | 5·8           |

From these results we are justified in drawing the conclusion that the formic aldehyde had no appreciable influence upon proteid metabolism in the case of this child. If, with the necessary restrictions, we regard the nitrogen excreted in the faeces as an index of the digestibility of the food, we find that in this case the addition of formic aldehyde to the proteid constituents of the food has been without influence in this direction. This is best seen from the average percentage of nitrogen in the faeces in the several periods. The assimilation and the balance are likewise not affected.

*Phosphorus Metabolism.*

The daily average of phosphorus in the food in the fore period was 1·05 g., of which 0·1922 were lost, being excreted in the faeces. Phosphorus was therefore assimilated to the extent of 81·70%. The relative excretion, &c., of phosphorus in the four periods we give in tabular form:—

|                              | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|------------------------------|--------------|--------------------|---------------------|---------------|
| Phosphorus of Food - - - - - | 1·05         | 0·84               | 0·79                | 0·81          |
| „ „ Urine - - - - -          | 0·3887       | 0·4385             | 0·3534              | 0·2146        |
| „ „ Faeces - - - - -         | 0·1922       | 0·2304             | 0·1991              | 0·2168        |
| „ Balance - - - - -          | +0·48        | +0·17              | 0·23                | +0·38         |
| „ Assimilation % - - - - -   | 81·70        | 72·57              | 74·80               | 73·24         |
| „ in dry Faeces % - - - - -  | 2·0          | 2·1                | 2·3                 | 2·3           |

From these figures it will be seen that the absolute quantity of phosphorus in the urine in the first formic aldehyde period is slightly increased (·05 g.), in the second formic aldehyde period it falls, however, slightly below the fore period value, and in the after period still further. As at the same time the assimilation of phosphorus as measured by the phosphorus excreted in the faeces is somewhat lessened, it would seem that during the first period formic aldehyde tended to stimulate phosphorus metabolism. The absolute changes are, however, so small, that they can only be regarded as indicating what might be the possible effect of formic aldehyde in much larger doses.

*Fat Assimilation.*

The daily average of fat in the food during the fore period was 43·42 g.; of this, 2·61 was lost, being excreted with the faeces, leaving a balance of + 40·81 g. The assimilation, therefore, amounted to 93·99%. These results and those of the following periods are recorded in tabular form:—

|                            | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|----------------------------|--------------|--------------------|---------------------|---------------|
| Fat in Food - - - - -      | 43·42        | 39·59              | 38·90               | 38·01         |
| „ „ Faeces - - - - -       | 2·61         | 2·79               | 2·22                | 2·70          |
| „ Balance - - - - -        | +40·81       | +36·80             | +36·69              | +35·50        |
| „ Assimilation % - - - - - | 93·99        | 92·96              | 94·30               | 92·90         |
| „ in Faeces % - - - - -    | 27·1         | 25·6               | 25·8                | 28·7          |

From these figures it will be seen that the quantity of fat in the faeces during the formic aldehyde periods did not increase, if anything, decreased in proportion to the faeces. The fat assimilation and fat balance remain unaffected.

In connection with the fat in the faeces, we estimated the *lecithin* according to the method described above. The results expressed as a percentage of total fat are as follows:—

|                                        | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|----------------------------------------|--------------|--------------------|---------------------|---------------|
| Lecithin in Grammes of 100 Grammes Fat | 15.08        | 11.31              | 13.16               | 4.28          |

As we enter into this subject later, we would only point out here that formic aldehyde seemed to have an influence in diminishing the excretion of lecithin by the faeces, and that this influence extended into the after period.

Having considered the most important factors in metabolism as investigated by us and drawn the conclusion that formic aldehyde had little if any influence upon them, we turn our attention to certain other factors which, although of minor importance, ought not to be overlooked.

On referring to the chief table (Table II.),<sup>1</sup> it will be seen that the total *quantity of urine* in the first formic aldehyde period decreased, whilst the quantity of faeces, and especially their percentage of water, increased. In the second formic aldehyde period the quantity of urine increased slightly, whilst the quantity of faeces and their water percentage decreased. It would thus seem that formic aldehyde had a tendency to produce a retention of water by the body. A rise in the specific gravity of the urine occurred *pari passu* with its diminution of volume.

If we regard the *uric acid* figures during this observation, we shall see that the average excretion of uric acid during the first formic aldehyde period underwent a very slight diminution along with the total nitrogen, and this would justify us in concluding that the urea and ammonia varied in the same direction. The analytical figures, so far as concerns the average total *sulphuric acid* excretion, show that formic aldehyde exerted upon it a barely appreciable effect, suggesting in connection with the nitrogen figures above, if we draw conclusions from them at all, that formic aldehyde exerted a slightly inhibitory action upon the breaking up of proteids in the body. Even these conclusions can only be applied to the first formic aldehyde period.

The strongly antiseptic properties of formic aldehyde render an inquiry as to its effect upon intestinal putrefaction, as measured by the quantity of ethereal sulphates in the urine, of interest. If we refer to the absolute figures in Table II., we are forced to the conclusion that the slight diminution of ethereal sulphates which occurred during both formic aldehyde periods is not sufficient to indicate any inhibitory effect upon intestinal putrefaction.<sup>2</sup> This seems to show that when formic aldehyde is taken with the food in these proportions, it does not in healthy children occur as such in the intestines.

So far as concerns body weight, it will be observed that there was a slight increase in the two formic aldehyde periods, which seems, however, to be due not to an increased flesh formation or fat retention, but to a retention of water as indicated by the diminished excretion of water in the urine or faeces.

The results relevant to the observations made above are summarised in the following table:—

TABLE IIA.

|                    | Nitrogen Assimilation % | % N. of Dry Faeces. | Phosphorus Assimilation % | % P. of Dry Faeces. | Fat Assimilation % | % Fat of Dry Faeces. | $\frac{A^*}{B}$ | $\frac{N^{**}}{SO_3}$ |

$$* \frac{A}{B} = \frac{\text{Inorganic } SO_3}{\text{Ethereal } SO_3}$$

$$** \frac{N}{SO_3} = \frac{\text{Nitrogen of Urine}}{SO_3 \text{ of Urine}}, \text{ measuring the degree of proteid metabolism.}$$

#### Observation II.—Child B.

The child was a healthy boy, aged five years, weighing 17.2 kilos, and remained in good health throughout the whole observation. He consumed daily 250 g. of bread, 600 cc. of milk, 20 g. of butter, 50 g. of meat, 50 g. of apple compote, 10 g. of sugar, 50 cc. of water, and 5 g. of toffee. The duration and arrangement of the observation was as in Child A. The formic aldehyde was administered in an identical manner and dose, but as in this case the total food was slightly increased, the proportion of formic aldehyde in it was slightly less. The analytical results obtained throughout this observation are recorded in the following table:—

<sup>1</sup> In these remarks throughout the entire paper, we refer to the average daily excretion in question.

<sup>2</sup> The ratio of total sulphuric acid to actual sulphuric acid is likewise not affected, further, as has been pointed out by many observers, this ratio is of no special importance.

Appendix.

## Appendix.

The results expressed in the above table are graphically represented in the following curves :—

Curve III.

Showing the influence of formic aldehyde upon nitrogen and phosphorus metabolism, etc

Curve IV.

Showing the influence of formic aldehyde upon fat assimilation and the quantity of faeces and urine.

*Nitrogen Metabolism.*

Adopting the same method of reasoning as in Observation I. we arrive at the following results with regard to the nitrogen balance and assimilation. These are best expressed in a tabular form.

|                             | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|-----------------------------|--------------|--------------------|---------------------|---------------|
| Nitrogen of Food - - - - -  | 7.68         | 8.23               | 7.95                | 8.80          |
| „ „ Urine - - - - -         | 5.83         | 6.12               | 5.85                | 6.57          |
| „ „ Faeces - - - - -        | 0.62         | 0.62               | 0.54                | 0.66          |
| „ Balance - - - - -         | +1.23        | +1.49              | +1.56               | +1.57         |
| „ Assimilation % - - - - -  | 89.82        | 92.46              | 93.21               | 92.50         |
| „ in dry Faeces % - - - - - | 6.0          | 5.4                | 5.0                 | 6.0           |

From these results we can draw the conclusion that formic aldehyde in both periods, seemed to have a slightly beneficial effect upon proteid assimilation. This is indicated by a rise in the percentage of nitrogenous food assimilated. The nitrogen percentage of the faeces shows a diminution. This result may find an explanation in a stimulating action of formic aldehyde upon the secretion of the digestive enzymes.

*Phosphorus Metabolism.*

The results in this connection expressed in a tabular form are as follows:—

|                              | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|------------------------------|--------------|--------------------|---------------------|---------------|
| Phosphorus of Food - - - - - | 1.09         | 0.97               | 0.92                | 0.95          |
| „ „ Urine - - - - -          | 0.6088       | 0.4859             | 0.5413              | 0.4845        |
| „ „ Faeces - - - - -         | 0.2286       | 0.2984             | 0.2842              | 0.2750        |
| „ Balance - - - - -          | +0.26        | +0.19              | +0.12               | +0.19         |
| „ Assimilation % - - - - -   | 79.03        | 69.23              | 69.11               | 71.05         |
| „ in dry Faeces % - - - - -  | 2.2          | 2.6                | 2.6                 | 2.5           |

From the above table it will be seen that the absolute differences in the several periods are small. Nevertheless if any positive conclusion may be drawn, it is in this case the formic aldehyde had a slightly depressing effect upon the assimilation of phosphorus as expressed by the slight increase of the phosphorus in the faeces. It must not be overlooked that the percentage figures in this case are a very large magnification of the absolute variations in amount. The formic aldehyde seemed to have no influence in stimulating the breaking down of the phosphorus-containing substances in the body itself; in fact there seems to be a suggestion, from the diminished amount of phosphorus in the urine, that it acted in the opposite direction.

*Fat Assimilation.*

As in the preceding cases, we express these results for the sake of convenience in the following table:—

|                             | Fore Period. | First F. A. Period. | Second F. A. Period. | After Period. |
|-----------------------------|--------------|---------------------|----------------------|---------------|
| Fat in Food - - - - -       | 43.98        | 42.73               | 42.09                | 43.78         |
| „ „ Faeces - - - - -        | 2.62         | 2.72                | 2.68                 | 2.42          |
| „ Balance - - - - -         | +41.36       | +40.01              | +39.43               | 3.50          |
| „ Assimilation % - - - - -  | 94.05        | 93.63               | 93.63                | 94.47         |
| „ in dry Faeces % - - - - - | 25.7         | 23.7                | 24.8                 | 22.1          |

From these figures it will be seen that the remarks we made with regard to the effect of formic aldehyde upon fat assimilation in Observation I. hold good in this case—viz., that there is no influence.

## Appendix.

In so far as concerns lecithin the following figures express our result :—

|                                        | Fore Period. | First F.A. Period. | Second F.A. Period. | After Period. |
|----------------------------------------|--------------|--------------------|---------------------|---------------|
| Lecithin in Grammes of 100 Grammes Fat | 21.09        | 22.60              | 14.59               | 17.30         |

Formic aldehyde seems to have the same influence here as in Observation I.

With regard to the remaining factors of general metabolism, in this case it will be seen from the chief table (Table III.) that the *quantity of urine*, as in Observation I., decreased in the first formic aldehyde period, but that the influence upon the quantity of faeces and their water content is less marked. In the second formic aldehyde period the quantity of urine continued to be less than that of the fore period, whilst the *quantity of faeces* and their water content remained practically constant. In the after period the quantity of urine increased to an amount exceeding that of the fore period. The quantity of faeces and their water content remained also in this period constant. It would seem therefore, as in the former case, formic aldehyde had a tendency to cause a retention of water in the body. The reaction of the urine remained acid through the whole observation. The *uric acid* excretion diminished to some extent in the formic aldehyde period, while the total nitrogen and the total sulphuric acid remained practically unaffected. If the slightness of the changes do not preclude us from drawing any conclusions at all, we should infer that in this case formic aldehyde exerted a specific action upon either the formation or retention of uric acid. The result in this case is the more interesting in that this child seemed to belong to the uric acid type. Under the influence of formic aldehyde the *ethereal sulphates* of the urine underwent a slight diminution; this was more pronounced than in Observation I. There seemed, however, to be practically no action upon intestinal putrefaction. We are the more entitled to draw this conclusion as the indoxyl reaction was equally intense throughout the whole observation. The *body weight* as in the former observation went up in the formic aldehyde period and remained constant in the after period. The increase in the formic aldehyde periods must be ascribed rather to a retention of water than to actual growth. We may epitomise the above observations in tabular form as follows :—

TABLE IIIA.

|                       | Nitrogen Assimilation % | % N. in Dry Faeces. | Phosphorus Assimilation % | % P. in Dry Faeces. | Fat Assimilation % | % Fat in Dry Faeces. | $\frac{A^*}{B}$ | $\frac{N^{**}}{SO}$ |
|-----------------------|-------------------------|---------------------|---------------------------|---------------------|--------------------|----------------------|-----------------|---------------------|
| Fore Period . . .     | 91.42                   | 6.1                 | 81.00                     | 2.0                 | 93.99              | 27.1                 | 16.7            | 6.1                 |
| First F.A. Period . . | 91.22                   | 5.9                 | 72.57                     | 2.1                 | 92.96              | 25.6                 | 15.5            | 6.4                 |
| Second F.A. Period .  | 91.99                   | 5.9                 | 74.80                     | 2.3                 | 94.30              | 25.8                 | 16.9            | 6.1                 |
| After Period . . .    | 92.38                   | 5.8                 | 73.24                     | 2.3                 | 92.93              | 28.7                 | 15.5            | 6.1                 |

$$* \quad \frac{A}{B} = \frac{\text{Inorganic } SO_3}{\text{Ethereal } SO_3}$$

$$** \quad \frac{N}{SO_3} = \frac{\text{Nitrogen of Urine}}{\text{SO}_3 \text{ of Urine}} \quad \text{measuring the degree of proteid metabolism.}$$

## Observation III.—Child C.

This child was a delicate girl, aged four years; she was convalescent from pneumonia, and was, as compared with the other children, ill nourished, and poorly developed. Her weight was 15 kilos. She consumed daily 200 g. of bread, 550 cc. of milk, 20 g. of butter, 30 g. of meat, 50 g. of apple compote, 10 g. of sugar, 50 cc. of water, 5 g. of toffee. The observation lasted for twenty-one days; seven days were used as fore period, seven days as formic aldehyde period, and seven days as after period. The method of administering the formic aldehyde was the same as in the previous observations, but it was given in this case throughout in a concentration of 1 in 5,000 of milk, occasionally some of the formic aldehyde was given in the meat; the total food was formalised to the extent of 1 in 9,000. The total quantity given per diem was 0.1 g. The child's general health and behaviour did not seem to be affected in any way throughout the whole observation.

The results expressed in the table on pages 330 and 331 are graphically represented in the following curves :—

Curve V.

Showing the influence of formic aldehyde upon phosphorus and nitrogen metabolism.

Curve VI.

Showing the influence of formic aldehyde upon fat assimilation and upon the quantity of urine and faeces.

The analytical results obtained throughout this observation are recorded in the following table :—

## Appendix.

## Appendix.

*Nitrogen Metabolism.*

Following the same methods as before, the results in this connection are expressed in tabular form as follows:—

|                                   | Fore Period. | F. A. Period. | After Period. |
|-----------------------------------|--------------|---------------|---------------|
| Nitrogen in Food per diem - - - - | 6.65         | 7.01          | 6.99          |
| „ „ Urine „ „ - - - -             | 4.84         | 5.13          | 5.29          |
| „ „ Faeces „ „ - - - -            | 0.54         | 0.77          | 0.68          |
| „ Balance „ „ - - - -             | +1.27        | +1.11         | +1.02         |
| „ Assimilation % - - - -          | 91.88        | 89.01         | 90.27         |
| „ in dry Faeces % - - - -         | 6.4          | 5.7           | 6.2           |

From these figures, speaking generally, we cannot say that the nitrogenous metabolism was to any extent affected. The quantity of nitrogen in the faeces, however, was certainly increased, and the effect seemed to be prolonged into the after period. The difference in absolute quantity as compared to the fore period is, however, very small (0.23 grammes in the formic aldehyde period, and 0.14 grammes in the after period). If one were to regard this result superficially, one would be tempted to at once draw the conclusion that formic aldehyde in this proportion, viz., 1 in 5,000, had rendered the proteid constituents of the food less digestible. Upon closer inspection, however, it seems that this increase of nitrogen in the faeces is rather to be explained by formic aldehyde exerting a slight irritant action upon the intestine, involving an increased shedding of epithelial cells. We are brought to this conclusion by the fact that the total quantity of the faeces was increased, and that the effect was prolonged into the after period. In this connection, however, we must not overlook the possibility of formic aldehyde exerting an inhibitory action upon the secretion of the digestive enzymes. As we shall discuss this later in another connection we shall say nothing further about it here.

*Phosphorus Metabolism.*

The results in this connection expressed in a tabular form are as follows:—

|                                     | Fore Period. | F. A. Period. | After Period. |
|-------------------------------------|--------------|---------------|---------------|
| Phosphorus of Food per diem - - - - | 0.81         | 0.79          | 0.82          |
| „ „ Urine „ „ - - - -               | 0.3835       | 0.4270        | 0.3833        |
| „ „ Faeces „ „ - - - -              | 0.1760       | 0.3050        | 0.4087        |
| „ Balance - - - -                   | +0.25        | +0.06         | +0.08         |
| „ Assimilation % - - - -            | 78.28        | 61.89         | 50.16         |
| „ in dry Faeces % - - - -           | 2.1          | 2.2           | 3.7           |

From these figures we come to the conclusion that the phosphorus balance, although approaching nearer to the equilibrium during the formic aldehyde, and after period, never actually reached it, and hence cannot be considered to have been seriously affected. On the other hand, reasoning from the increased amount of phosphorus in the faeces, there can be no doubt that, speaking generally, the phosphorus of the food has not been assimilated during the formic aldehyde and after periods, to the same extent as during the fore period. Further, taking into consideration the increased amount of phosphorus in the urine during the formic aldehyde period, along with the diminished assimilation and the fact that the phosphorus in the food remained constant, formic aldehyde seemed to exert a slight stimulating action upon the breaking down of the body proteids rich in phosphorus.

As this case affords the first example of tangible increase in the phosphorus of the faeces, we examined it more carefully. Keeping in mind the results of the experiments *in vitro*, a probable explanation appeared to be that the formalisation of the proteid constituents of the food had rendered them less susceptible to the action of the pancreatic secretion. It must be remembered, however, in this connection that the pancreatic juice acts upon the residue of gastric digestion, the phosphorus containing compounds of which are chiefly nucleo-proteids and nucleo-albumins. An indication of the extent to which pancreatic digestion was deranged would be given by an estimation of the nucleo-proteid and nucleo-albumin phosphorus in the faeces. This we proceeded to do, following generally the method described by Knopfmacher<sup>1</sup> and modified by Muller.<sup>2</sup> It must be noted at once, however, that this method is not an absolute analytical one, but simply comparative.<sup>3</sup>

Another possible explanation of the increased amount of phosphorus in the faeces would be an increased excretion of lecithin with them. Our attention was drawn to the possibility of this explanation by the fact, as will be seen later, that the substances soluble in ether in the faeces were actually increased during the formic aldehyde period. We proceeded, therefore, to estimate the phosphorus due to lecithin, and found it, contrary to our expectation, to have considerably decreased during the formic aldehyde period.

Having obtained the figures for phosphorus due to lecithin and due to nucleo-proteids, we were enabled, by subtraction of their sum from the total phosphorus, to obtain a phosphorus value representing in all probability inorganic phosphorus.

<sup>1</sup> Wiener klin. Wochenschr., 1898, no. 45.

<sup>2</sup> Zeitschr. f. Biologie, 1900, p. 451.

<sup>3</sup> The faeces (about 5 g.) freed from fat were ground up with 200 cc. of dilute HCl containing some tannic acid, to fix the nucleo-proteid phosphorus. After twenty-four hours standing the mixture was filtered, and washed with the tannic acid HCl solution till 100 cc. of the washings contained no trace of phosphoric acid. Phosphorus was then estimated in the residue by Neumann's method, described under general methods.

These results in a tabular form are as follows :—

Appendix.

|                                  | Total P. | Nucleo<br>Proteid P. | Lecithin P. | Inorganic P. |
|----------------------------------|----------|----------------------|-------------|--------------|
| Fore Period - - - - -            | 0.1760   | 0.0085               | 0.0226      | 0.1459       |
| Formic Aldehyde Period - - - - - | 0.3050   | 0.0178               | 0.0086      | 0.2786       |
| After Period - - - - -           | 0.4087   | 0.0149               | 0.0264      | 0.3674       |

It will be seen from the above table that the nucleo-proteids of the faeces as measured by their phosphorus content are increased, and from this we are justified in concluding that formic aldehyde has exerted some influence upon their digestion. Since this effect is continued into the after period, the conclusion seems justified that it is due rather to a specific action upon the secretion of the pancreatic enzymes than to a diminished digestibility of the food. Whatever explanation of the increase in nucleo-proteids we may adopt, this latter is not sufficient of itself to explain the actual increase in the total phosphorus; much less does the lecithin afford an explanation of this. We are forced, therefore, to assume that the increased phosphorus excretion is due mainly to an increased excretion of what we have termed inorganic phosphorus. A further confirmation of this conclusion would be found in an increased excretion by the faeces of those bases with which phosphoric acid is usually combined in an insoluble form—viz., calcium and magnesium. A quantitative analysis of the faeces in this respect showed an actual increase, proportional to that of the inorganic phosphorus, in these bases during the formic aldehyde and after periods. The results are expressed in the following table :—

|                                  | % Ash of<br>Faeces. | Absolute Amount. |                  | % CaO<br>of Ash. | % MgO<br>of Ash. |
|----------------------------------|---------------------|------------------|------------------|------------------|------------------|
|                                  |                     | CaO<br>per diem. | MgO<br>per diem. |                  |                  |
| Fore Period - - - - -            | 22.11               | 0.6654           | 0.0674           | 3.58             | 0.36             |
| Formic Aldehyde Period - - - - - | 32.51               | 1.2139           | 0.1162           | 3.96             | 0.38             |
| After Period - - - - -           | 20.77               | 0.3688           | 0.0829           | 3.84             | 0.36             |

Taking all these results into consideration, we should be inclined to conclude that the increase of phosphorus in the faeces depends upon an increase in inorganic phosphorus, due to the co-operation of two causes. Firstly, to a stimulating action exerted by formic aldehyde, or, more probably, formic acid, upon the intestinal secretion; and, secondly, to a less extent, to an increased splitting up of lecithin and the transformation of the glycerophosphoric acid produced into insoluble phosphates.<sup>1</sup>

In this instance we thought the phosphorus metabolism sufficiently interesting to have its results incorporated in a curve.

#### Curve VII.

Representing graphically the phosphorus metabolism under formic aldehyde in a delicate child.

<sup>1</sup> Noel Paton (Journ. of Physiol., 1900) found that the calcium salt of glycerophosphoric acid administered to a goat was excreted in the faeces as inorganic phosphate

## Appendix.

*Fat Assimilation.*

The results are, as in former cases, represented in tabular form :—

|                             | Fore Period. | F.A. Period. | After Period. |
|-----------------------------|--------------|--------------|---------------|
| Fat in Food - - - - -       | 38.95        | 37.59        | 42.06         |
| " " Faeces - - - - -        | 1.77         | 3.10         | 1.95          |
| " Balance - - - - -         | + 37.18      | + 34.49      | + 40.11       |
| " Assimilation % - - - - -  | 95.46        | 91.75        | 95.37         |
| " in dry Faeces % - - - - - | 21.1         | 22.9         | 17.7          |

It will be seen from these figures that formic aldehyde interfered in this case with the assimilation of the fat of the food. The interference did not extend into the after period. From this latter fact we may conclude that in this case formic aldehyde exerted a specific action upon the fat splitting enzyme of the pancreas.

With regard to lecithin, we have already given the phosphorus corresponding to the lecithin, but following our previous procedure we now give the percentage of lecithin in the total fat.

|                                              | Fore Period. | F.A. Period. | After Period. |
|----------------------------------------------|--------------|--------------|---------------|
| Lecithin in grammes of 100 grammes fat - - - | 21.15        | 7.25         | 24.77         |

In this case the effect on the lecithin excretion is most marked. We are inclined to ascribe this decrease and that which took place in the other cases to formic aldehyde having exerted a stimulating effect upon the lecithin splitting ferment of the pancreas, which according to Bokai<sup>1</sup> splits up lecithin into glycerophosphoric acid, free fatty acids and cholin. That the decreased excretion of lecithin is not due to a retention of lecithin in the body by a direct absorption of it as such, may be concluded from the phosphorus balance.

On referring to the chief table, we see that the *quantity of urine* in this case was increased, in the formic aldehyde period, an exactly opposite effect to that observed elsewhere. The specific gravity of the urine fell during this period. With regard to the excretion of *uric acid*, also an opposite effect was produced, viz., an increase. As in the after period the average uric acid figure fell below the fore period level, we infer that either a dissolving out of uric acid from the tissues took place under formic aldehyde, or a stimulated production of it. The *total sulphuric acid* excretion was somewhat increased both during the formic aldehyde and the after periods; this together with a slightly increased total nitrogen excretion, suggest an effect upon general proteid katabolism in the inverse sense to that observed in Child A. The decrease in *etheral sulphuric acid* is too small to enable us to draw any conclusions other than negative ones from it. The indoxyl test remained constant through the whole observation. During the formic aldehyde and the after period the *body weight* increased, and this cannot be explained in this case, as in the preceding ones, by a retention of water in the body. This latter occurrence, together with the fact that the general health of the child remained unaffected during the formic aldehyde period, must tend to minimise any adverse deductions which may be made from the above results.

These observations may be summarised in tabular form as follows :—

TABLE IV A.

|                        | Nitrogen<br>Assimilation<br>% | % N.<br>of<br>Faeces. | Phosphorus<br>Assimilation<br>% | % P.<br>in dry<br>Faeces. | Fat<br>Assimilation<br>% | % Fat<br>in dry<br>Faeces. | $\frac{A^*}{B}$ | $\frac{N^{**}}{SO_3}$ |
|------------------------|-------------------------------|-----------------------|---------------------------------|---------------------------|--------------------------|----------------------------|-----------------|-----------------------|
| Fore Period - - -      | 91.88                         | 6.4                   | 78.28                           | 2.1                       | 95.46                    | 21.1                       | 12.0            | 6.1                   |
| Formic Aldehyde Period | 89.01                         | 5.7                   | 61.39                           | 2.2                       | 91.75                    | 22.9                       | 14.5            | 6.1                   |
| After Period - - -     | 90.27                         | 6.2                   | 50.16                           | 3.7                       | 95.37                    | 17.7                       | 15.8            | 6.1                   |

$$* \frac{A}{B} = \frac{\text{Inorganic } SO_3}{\text{Etheral } SO_3}$$

$$** \frac{N}{SO_3} = \frac{\text{Nitrogen of Urine}}{\text{SO}_3 \text{ of Urine}}, \text{ measuring the degree of proteid metabolism.}$$

Before proceeding to draw our general conclusions, for the sake of reference, we give in one diagram the results of the three observations expressed graphically, as far as regards the influence of formic aldehyde upon nitrogen, phosphorus, and fat assimilation, and body weight.

Appendix.

## Curve VIII.

Showing the influence of formic aldehyde upon the body weight and upon the nitrogen, phosphorus, and fat assimilation of three children.

Appendix.*General Conclusions.*

(1.) In healthy children formic aldehyde administered with the food in doses up to 1 : 5,000 in milk or 1 : 9,000 in total food and drink exerted no appreciable effect on the nitrogen or phosphorus metabolism, or fat assimilation.

The analytical figures suggest, however, that formic aldehyde has a tendency to diminish phosphorus and fat assimilation, and hence it may be inferred that in larger doses, or if continued for a longer period, it would act in this direction. This effect is referable to an influence upon pancreatic digestion.

(2.) In healthy children formic aldehyde in the above doses produces a retention of water in the body.

(3.) In a delicate child formic aldehyde in the above maximum dose had a chemically measurable deleterious effect upon the nitrogen, phosphorus and fat assimilation, again referable to an action upon the pancreatic digestion, combined with a slight intestinal irritant action. There was a slight tendency to stimulate the katabolism of proteid material.

(4.) In a delicate child formic aldehyde increased the volume of urine and the weight of fæces.

(5.) In all cases the excretion of lecithin in the fæces was diminished under the influence of formic aldehyde. This effect is probably referable to a stimulating action of formic aldehyde on the lecithin-splitting ferment of the pancreas.

(6.) In no instance did formic aldehyde exert any appreciable intestinal antiseptic action.

(7.) In no instance was there any influence on the general health or well-being of the children.

---

## APPENDIX No. VII. (c).

## REPORT ON THE INFLUENCE OF BORIC ACID AND BORAX UPON THE GENERAL METABOLISM OF CHILDREN; HANDED IN BY PROFESSOR TUNNICLIFFE, BEING A SERIES OF OBSERVATIONS MADE BY HIM IN CONJUNCTION WITH DR. OTTO ROSENHEIM.

Both boric acid and borax are extensively used as food preservatives, and much interest attaches to the question of their influence, if any, upon the general nutrition of the consumer, especially children. Although this method of preserving food has existed for a comparatively long period, there seems no agreement as to the harmfulness or otherwise of these substances when taken with a mixed diet.

The method most valuable for affording us reliable data upon which to base conclusions in this connection is that of comparative metabolic observations on the human subject, extending over a considerable period, and this method we have adopted.

Before entering fully into our own work in this direction, we shall briefly criticise the data from which up to the present the conclusions concerning the harmfulness or otherwise of boric acid and borax as food preservatives have been based.

*Literature.*—The literature may be summarised as consisting of (I.) experiments made on the influence of these substances upon digestions *in vitro*; (II.) experiments made on animals as to the effect of prolonged small doses upon their general health and metabolism; (III.) general action on man, and one metabolic experiment made on one man.

I. Experiments made upon the influence of boric acid and borax upon digestions *in vitro*.

Comparative qualitative experiments have been carried out in this connection by Hehner<sup>1</sup>, Weber<sup>2</sup>, F. Allen<sup>3</sup>, Cripps<sup>4</sup>, Leffmann<sup>5</sup>, Liebreich<sup>6</sup>, Halliburton<sup>7</sup>. Quantitative experiments have also been made by Chittenden<sup>8</sup>, Maybery and Goldsmith<sup>9</sup>, Rideal and Foulerton<sup>10</sup>, and Liebreich<sup>11</sup>.

The outcome of the quantitative experiments, which confirm the qualitative ones, may shortly be summarised as follows:—

*Salivary Digestion.*—Boric acid favours the amylolytic action of saliva (Chittenden). Borax, on the other hand, has an inhibitory action on the conversion of starch by saliva (Weber, Chittenden, Rideal and Foulerton, Liebreich). This latter effect is shown by Liebreich to be an alkali action.

*Rennet Action.*—Boric acid either has no influence upon the action of rennet upon milk (Cripps, Halliburton) or hastens it (F. J. Allen). Borax, according to the concentration, delays or prevents rennet action (F. J. Allen, Halliburton). By the addition of small quantities of calcium chloride, however, the rennet action takes place in the presence of borax (Allen). It is interesting in this connection to note that sodium chloride has the same action as borax<sup>12</sup>.

*Gastric Digestion.*—Boric acid in large doses favours gastric proteolysis<sup>13</sup> (Chittenden). Borax in small doses has also a slight stimulating action (Chittenden, Rideal and Foulerton), whilst in large doses, proportionally to the increasing alkalinity, it has a retarding effect (Chittenden).

*Pancreatic Digestion.*—(a) Proteolysis. Borax in small and large doses, proportionately to its concentration, stimulates markedly pancreatic proteolysis (Chittenden). Boric acid (and boric mixture) have a distinct inhibitory action. (b) Amylolysis. Borax mixture exerts a retarding action on the conversion of starch by commercial pancreatic extract (Rideal and Foulerton). Borax itself has a slight retarding action, whilst boric acid has no action (Liebreich).

The results of the above observers seem to justify the conclusion that (the radicle of) boric acid and borax as such exerts no specific action, the effect in each case being referable to the acid, or alkali moiety, all digestions taking place in an acid medium being inhibited by borax, those occurring in an alkaline medium by boric acid.

II. *Experiments made upon Animals.*—(a) Effect of prolonged small doses. Animals have been fed for different periods with food containing various quantities of borax and boric acid by several observers—(Neumann<sup>14</sup>, Annett<sup>15</sup>, Rideal<sup>16</sup>, Liebreich<sup>17</sup>). The outcome of these experiments is shortly that boric acid and borax given in small doses for prolonged periods has no influence on the general health of animals (Neumann, Rideal, Liebreich).

Excessive doses (10 grammes or more, according to body weight) produced transient nausea and vomiting.

To elucidate the question of the effect of boric acid upon young animals<sup>18</sup> a series of experiments were made upon young sucking pigs by A. D. Hall and H. S. Hammond, in collaboration with ourselves, at the South-Eastern Agricultural College, Wye. These observations\* show that 0.2 to 2.4 grammes boric acid per diem, continued for seven weeks, added to a mixed weighed diet, had no influence upon the live weight, growth, and general health of the animals.

(b) Metabolic experiments on animals have been made by Cyon<sup>19</sup>, Gruber<sup>20</sup>, Chittenden and Gies<sup>21</sup>, and Liebreich<sup>22</sup>

Appendix. Chittenden and Gies's experiments are very complete and accurate, and in their paper will be found a detailed criticism of the earlier less complete work. The chief conclusions from Chittenden and Gies's work are best given in their own words shortly as follows:—

Moderate doses of borax up to 5 grammes per day, when continued for some time, are without influence upon proteid metabolism and do not exert any general nutritional changes of the body. Large doses of borax, 5-10 grammes daily, have a direct stimulating effect upon proteid metabolism. They tend to retard somewhat the assimilation of proteid and fatty foods, increasing notably the weight of the faeces and their contents of nitrogen and fat.

Boric acid in doses up to 3 grammes per day is practically without influence upon proteid metabolism and general nutrition.

Neither boric acid nor borax affects intestinal putrefaction.

Liebriech's experiment with borax on a dog confirmed Chittenden and Gies's results.

### III. General action on Man, &c.

There is abundant evidence that boric acid and borax can be taken by man in considerable doses over long periods in the food or by itself, without producing any toxic effect.<sup>1</sup> It is also, however, definitely established that in certain patients medicinal doses (1 gramme two or three times a day) give rise to transient erythematous eruptions after relatively short periods. It is, however, to be noted that these eruptions were, so far as we are aware, invariably produced by the use of boric acid or borax as a drug, no case being reported of the occurrence of rashes caused by these substances in food. How far these rashes depend on idiosyncrasy and are comparable to those produced by shell-fish, strawberries, &c., is outside our purpose to discuss here.

The only metabolic experiment made on man published up till now is one by Forster.<sup>2</sup> The action of boric acid alone on one man was examined. Two relatively short series of experiments were made. In the first 3 grammes of boric acid were given daily for three days with a mixed diet. The second experiment consisted of two periods of two days each in which the subject, an adult man, took 1.5 and 0.5 grammes of boric acid per diem respectively with a milk diet. Forster's conclusions, which appear to have been much more cautiously expressed by himself than by his abstractors, are that boric acid has no influence on proteid metabolism and fat assimilation. He found, however, that the total quantity of faeces and their nitrogen and phosphorous percentage were slightly increased. Forster is inclined to ascribe this to a slightly diminished assimilation, together with an increased epithelial and mucuous excretion from the intestine. (This latter, however, he regards as being purely hypothetical.) He also concludes that boric acid may possibly exert an intestinal antiseptic action, as indicated by the slight decrease of the ethereal sulphates in the urine.

Lehmann, in his "Methoden der prakt. Hygiene, 1901," states that the results of an observation made under his direction by K. Mann upon the latter's own metabolism (not yet published) did not confirm those of Forster.

### GENERAL ARRANGEMENT AND METHOD OF OUR OBSERVATIONS.

Before entering into the details especially relevant to our own observations it might be well to recapitulate briefly the general principles of metabolic experiments. They consist in the exact estimation of the quantity of food and its various constituents during a given period and the estimation during the same period of the total excreta and their constituents, chiefly with regard to nitrogen, phosphorus, fat, &c. By this means we get valuable information with regard to the assimilation of these substances by, and their retention in the body. We should like to point out, however, that there is a slight fallacy in this reasoning, in that our knowledge of the origin of faecal nitrogen is somewhat limited. According to Praussnitz,<sup>3</sup> the whole of the nitrogen in the faeces arises not from the unabsorbed nitrogen of the food, but from the intestinal secretion (epithelial cells, &c.). The value of the metabolic method is not to any extent affected by this, in so far as all nitrogen excreted by the faeces must be regarded as lost to the body, and its subtraction from the quantity of nitrogen ingested gives us the quantity of nitrogen retained. It must, however, be observed at once, as has been emphasized by Pawlow,<sup>4</sup> that the results of these experiments give us no absolute information with regard to the actual digestibility of any given food, in so far as we are left by them in complete ignorance of the amount of energy spent by the organism in producing the observed effect. Provided the organism is equal to the occasion an indigestible food might be as well assimilated and retained as a digestible one, but to produce this result an additional output of energy would be required. If this additional output of energy were relatively small we should probably have no indications with regard to it; but were it relatively large, or, in other words, were the difference in the digestibility of the foods in question great, we should probably find that the body weight or the general health of the person under observation would be affected, and this effect would be the more noticeable the longer the period of observation, and the more sensitive the person chosen. On general principles, we thought it advisable to allow, from these reasons, our observations to extend over comparatively long periods, and to take what were *a priori* to be regarded as relatively sensitive re-agents—viz., children both robust and delicate, and to observe minutely during the various periods their general health and behaviour. From another standpoint children had, in this connection, an additional interest, on account of the fact that milk forms so large proportion of their diet, and it is to milk that boric acid and borax, as preservatives, are generally added.

Our observations were made upon three children, two of whom (boys) might be regarded as typically healthy, and were aged 2½ and 5 years, the third child (girl aged 4 years) was delicate, being convalescent from pneumonia. We shall refer to the children subsequently as A. B. and C. respectively. During the whole period the children were under our perpetual observation, and absolute control was kept over all ingesta, which were accurately weighed by us, and excreta which were collected in diurnal periods without loss. The general conditions of their life remained constant; they were kept for some time before the "fore period" of the observation began under identical conditions to those obtaining during the observation; they took each day the same amount of exercise, and their habits were in every respect regular. The research was carried out during the months of May and June, and extended in the case of B and C over a period of twenty-two days, in the case of A over one of twenty-five days. Each period was sub-divided into four: a fore, a boric acid, a borax, and an after period. The relative lengths of these periods will be seen from the tables. The children had a mixed diet. With regard to the quantities of the different food stuffs we were guided at first by the work of Camerer.<sup>5</sup> This was subsequently modified to a small extent by our own observations concerning the establishment of nitrogenous equilibrium in which the children were approximately placed before the fore period began. Every article of food was carefully analysed, with regard to its percentage composition, and in no case were so-called average figures taken.

In order to minimise the amount of analytical work entailed by this method the three children were supplied from the same stock of foods, which were taken originally in as large a quantity as was consistent with their keeping properties. To this end Pasteurised milk was supplied to us in bottles, each lot of bottles being taken from the same churn.<sup>6</sup> Each lot of meat lasted for about four days, lean beef was usually taken, and the whole stock minced; a sample of this was then analysed.

| Toffee - - -       | —                 | 3.14    | 4.33  | 76.95                 | 0.03       | —                 | —     |

The excreta were collected without loss in twenty-four hour periods from 8 a.m. to 8 a.m., and worked up the same day. The faeces were weighed in their normal state each day, small quantities of acid added when necessary, and subsequently evaporated on a water-bath. When dry they were finely powdered and analysed. The faeces belonging to each period were separated by means of the administration of powdered charcoal.

**Methods of Analysis.**—All nitrogen estimations were made by Gunning's<sup>1</sup> modification of Kjeldahl's method. It was found advantageous, especially in the analysis of the faeces, to add a few crystals of copper sulphate to the mixture of sulphuric acid and potassium sulphate, as by this means a very rapid and quiet oxidation was obtained. Two methods of phosphorus estimation were used. In food, faeces, and urine the total phosphorus was estimated by Neumann-Keller's method<sup>2</sup>—viz., by oxidation in a Kjeldahl's flask by means of nitric acid and ammonium nitrate, subsequent precipitation with molybdic solution, &c., and weighing as magnesium pyrophosphate. For the estimation of lecithin phosphorus in the ethereal extract of the faeces the usual process was used (oxidation by means of a mixture of sodium carbonate and nitrate), and subsequent estimation of the phosphorus as before. The carbohydrates were estimated gravimetrically as dextrose or lactose by means of Fehling's solution. The fats, which term includes all the ether soluble substances, were estimated by extraction in Soxhlet's apparatus, after previous treatment with alcohol, according to E. V. Voit.<sup>3</sup> Lecithin was estimated by multiplying the phosphorus figure obtained from the filtered ethereal extract of the faeces with the factor 7.27, corresponding to distearyl-lecithin. The Uric acid was determined by our own modification of Hopkin's method.<sup>4</sup> The total and ethereal sulphuric acids were estimated according to Baumann's method.<sup>5</sup>

#### Observation I. Child A.

The child was a healthy boy, aged 2½ years, weighed 15.3 kilos, and remained in good health during the whole observation. He consumed daily as follows :—200 grammes of bread, 550 cc. of milk, 20 grammes of butter, 30 grammes of meat, 50 grammes of apple compote, 10 grammes of sugar, 50 cc. of water, and 5 grammes of toffee. This diet was well taken and adhered to throughout the experiment. The whole observation extended over twenty-five days, eight days being taken as a fore period, and five days as an after period. The intermediate period of twelve days consisted of a boric acid period of seven days and a borax period of five days. The pure substances—boric acid or borax, as the case may be—were added to 500 cc. of the daily milk early in the morning, and were administered as shown in the following table :—

##### Boric Acid Period.

3 days : 0.5 g. per diem = 1 : 1000 in Milk = 1 : 1800 in total Food and Drink.  
 3 days : 0.66 g. " = 1 : 760 " = 1 : 1370 " " "  
 1 day : 1 g. " = 1 : 500 " = 1 : 900 " " "

##### Borax Period.

5 days : 1.5 g. per diem = 1 : 330 in Milk = 1 : 600 in total Food and Drink.

It may be noted here that the maximum medicinal dose for this child would be 0.2 g. of boric acid and 0.27 g. of borax, also that the quantities given are greatly in excess of those required for the preservation of milk.<sup>6</sup>

The analytical results obtained throughout the observation are recorded in the following table :—

<sup>1</sup> Zeitschr. für analyt. Chemie, 1899, p. 89.

<sup>2</sup> Zeitschr. für Physiol. Chemie, xxix., p. 151.

<sup>3</sup> Zeitschr. für Biol., xxvii., p. 555.

<sup>4</sup> Centralbl. f. Physiol., 1897, p. 434. It has been shown by the most recent workers that the initial precipitation of uric acid by means of ammonium chloride is just as reliable as the more complicated method of Salkowski Ludwig when certain conditions are observed. Ritter, Folin, Wörner, etc.

## Appendix.

The results expressed in the above table are graphically represented in the following curves:—

Curve I.

-Shewing the influence of boric acid and borax upon nitrogen and phosphorus metabolism, etc.

Curve II.

Showing the influence of boric acid and borax upon fat assimilation and the quantity of faeces and urine.

Referring to the tables and curves relating to Child A, we purpose classifying our remarks under the following headings:—

*Nitrogen-Metabolism.*

In the fore period the daily quantity of nitrogen taken in the food was 6.99 g., of which 0.65 g. were not assimilated, being lost with the faeces, corresponding to 9.3 %. The assimilation of nitrogen in the fore period amounted therefore to 90.70 %.

With the urine 4.88 g. of nitrogen were excreted, and if this amount be subtracted from the amount assimilated, we obtain a daily balance of +1.45 g. nitrogen.

To avoid repetition we give the results with regard to the nitrogen balance and assimilation during the different periods in tabular form:—

|                             | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-----------------------------|--------------|--------------------|---------------|---------------|
| Nitrogen in Food . . . . .  | 6.99         | 6.29               | 6.20          | 6.29          |
| „ „ Urine . . . . .         | 4.88         | 5.41               | 4.62          | 5.49          |
| „ „ Faeces . . . . .        | 0.65         | 0.62               | 0.59          | 0.72          |
| Balance . . . . .           | +1.45        | +0.26              | +0.98         | +0.08         |
| Assimilation % . . . . .    | 90.70        | 90.14              | 90.48         | 88.56         |
| „ % in dry Faeces . . . . . | 6.0          | 5.7                | 6.5           | 6.5           |

From these results we are justified in concluding that neither boric acid nor borax exert any influence upon the assimilation of proteids. The tendency of the body to reach nitrogenous equilibrium is clearly shown in the balance figures. From the amount of nitrogen excreted in the urine during the respective periods we may perhaps draw the conclusion that boric acid in this instance tends slightly to increase, and borax slightly to inhibit proteid katabolism.

*Phosphorus Metabolism.*

The daily average quantity of phosphorus in the food during the fore period was 0.77 g., of which 0.2359 g. were lost, being excreted with the faeces. Phosphorus was therefore assimilated to the extent of 69.36%. The relative excretion, etc., of phosphorus in the four periods we give in tabular form.

|                              | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|------------------------------|--------------|--------------------|---------------|---------------|
| Phosphorus in Food . . . . . | 0.77         | 0.80               | 0.81          | 0.80          |
| „ „ Urine . . . . .          | 0.3704       | 0.4515             | 0.4272        | 0.5045        |
| „ „ Faeces . . . . .         | 0.2359       | 0.2315             | 0.2048        | 0.2613        |
| Balance . . . . .            | +0.17        | +0.12              | +0.18         | +0.04         |
| Assimilation % . . . . .     | 69.36        | 71.06              | 74.82         | 67.34         |
| „ in dry Faeces . . . . .    | 2.2          | 2.1                | 2.2           | 2.4           |

These figures show that the phosphorus metabolism was not affected by boric acid and borax. The “assimilation” of phosphorus was, if anything, improved during the drug periods.

*Fat Assimilation.*

The daily quantity of fat in the food during the fore period was 35.53 grammes. The fat excreted with the faeces was 2.42 grammes. The assimilation therefore amounted to 93.19 %. These results, and those of the following periods are recorded in tabular form as follows:—

|                               | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-------------------------------|--------------|--------------------|---------------|---------------|
| Fat in Food . . . . .         | 35.53        | 37.16              | 39.00         | 41.68         |
| „ „ Faeces . . . . .          | 2.42         | 2.65               | 1.89          | 2.14          |
| Fat balance . . . . .         | +33.10       | +34.51             | +37.11        | +39.53        |
| Assimilation % . . . . .      | 93.19        | 92.87              | 95.19         | 94.87         |
| Fat in dry Faeces % . . . . . | 23.0         | 24.3               | 20.8          | 19.5          |

## Appendix.

It will be seen from these figures that the amount of fat retained by the body rose with the amount of fat in the food. If anything the assimilation of fat was increased during the borax period.

The chief remaining points of interest brought out by this observation are as follows<sup>1</sup> :—

The *quantity of urine* underwent slight variations during the drug periods in the direction of an increase. The increase was more marked during the boric acid period.

The *specific gravity* diminished as the volume increased.

The *reaction*, alternating between acid and amphoteric (litmus) during the fore period, remained constantly amphoteric during the boric acid period, and constantly acid during the borax period.

The *quantity of faeces* remained practically unaltered with the exception of the borax period, in which the average daily quantity is slightly decreased.

The increase in *uric acid* is too slight to permit of any conclusions being drawn from it.

The quantity of total *sulphuric acid* increased slightly in the boric acid period, indicating, with the slight increase of nitrogen in the urine, a tendency to stimulate proteid katabolism.

The *etheral sulphates* were slightly increased during both periods to an equal extent. Intestinal putrefaction was, therefore, certainly not diminished by either substance, as was also shown by the comparative indoxyl-reactions.

The boric acid could easily be demonstrated in the urine on the first day of its administration, and disappeared completely in the course of the second day of the after period. These results show clearly that both boric acid and borax are rapidly eliminated from the body, and confirm the results of previous workers.<sup>2</sup>

During the boric acid and borax periods the child gained in weight.

The results relevant to the observations made above are summarised in the following table :—

TABLE IIIA.

$\frac{A}{B} = \frac{\text{Inorganic } SO_3}{\text{Etheral } SO_3}$

\*\*  $\frac{N}{SO_3} = \frac{\text{Nitrogen of Urine}}{SO_3 \text{ of Urine}}$  measuring the degree of proteid metabolism.

## Observation II. Child B.

The child was a healthy boy, aged five years, weighing 18.5 kilos, and remained in good health during the whole observation. He consumed daily 250 g. of bread, 600 cc. of milk, 20 g. of butter, 50 g. of meat, 50 g. of apple compote, 10 g. of sugar, 50 cc. of water, and 5 g. of toffee. The whole observation lasted for twenty-two days. The fore period in this case lasted for five days, otherwise the arrangement and quantity of boric acid and borax given were the same as in Observation I. These substances were administered as shown in the following table :—

## Boric Acid Period.

3 days : 0.5 g. per diem = 1 in 1000 milk, 1 in 2000 total food and drink.

3 days : 0.66 g. „ = 1 in 760 „ 1 in 1500 „ „ „

1 day : 1.0 g. „ = 1 in 500 „ 1 in 1000 „ „ „

## Borax Period.

5 days : 1.5 g. per diem = 1 in 330 milk, 1 in 660 total food and drink.

It may be noted here that the maximum medicinal dose for this child is in the case of boric acid 0.24 g., of borax 0.33 g., and that the quantities given, as in the former observation are greatly in excess of those which would be required as a food preservative.

<sup>1</sup> In these remarks throughout the entire paper we refer to the average daily excretion in question.

Chittenden and Gies (loc. cit.), where also references to former observers are given.

The results expressed in the table on pages 344 and 345 are graphically represented in the following curves : —

*Curve III.*

Showing the influence of boric acid and borax upon nitrogen and phosphorus metabolism, &c

*Curve IV.*

Showing the influence of boric acid and borax upon fat assimilation, and the quantity of faeces and urine.

The analytical results obtained throughout this observation are recorded in the following table —  
3017.

## Appendix.

Adopting the same method as in the previous observation we arrive at the following results :—

*Nitrogen Metabolism.*

|                                   | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-----------------------------------|--------------|--------------------|---------------|---------------|
| Nitrogen in Food - - - - -        | 8.64         | 7.77               | 7.75          | 7.85          |
| „ „ Urine - - - - -               | 6.46         | 6.61               | 6.35          | 6.39          |
| „ „ Fæces - - - - -               | 1.01         | 0.69               | 0.95          | 0.92          |
| Balance - - - - -                 | +1.17        | +0.47              | +0.45         | +0.54         |
| Assimilation - - - - -            | 88.31        | 91.12              | 87.74         | 88.28         |
| Nitrogen % in dry Fæces - - - - - | 6.7          | 6.1                | 6.9           | 6.9           |

From these figures it will be seen that the nitrogen metabolism underwent no change. The assimilation of the nitrogenous food was improved during the boric acid period, and practically not affected during the borax period. The tendency of the body to reach equilibrium is clearly seen in the balance figures. The variation of the nitrogen in the urine during the respective periods is very small, but may be regarded as pointing to a slight stimulation of proteid katabolism during the borac acid period and the reverse during the borax period.

*Phosphorus Metabolism.*

|                                     | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-------------------------------------|--------------|--------------------|---------------|---------------|
| Phosphorus in Food - - - - -        | 0.87         | 0.96               | 0.97          | 0.96          |
| „ „ Urine - - - - -                 | 0.4970       | 0.5378             | 0.5584        | 0.5247        |
| „ „ Fæces - - - - -                 | 0.4180       | 0.2574             | 0.3876        | 0.3124        |
| Balance - - - - -                   | -0.04        | +0.17              | +0.02         | +0.13         |
| Assimilation % - - - - -            | 51.72        | 73.30              | 60.04         | 67.46 %       |
| Phosphorus in dry Fæces % - - - - - | 2.9          | 2.3                | 2.8           | 2.3           |

From the above figures it will be seen that these drugs did not affect the phosphorus metabolism, but that the assimilation of phosphorus was rather improved by them, especially by boric acid. Taking into consideration the fact that the phosphorus in the food was increased during the drug periods, the slight increase of phosphorus in the urine cannot be regarded as pointing to an increased phosphorus katabolism.

*Fat Assimilation.*

|                            | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|----------------------------|--------------|--------------------|---------------|---------------|
| Fat in Food - - - - -      | 37.59        | 40.54              | 40.87         | 43.30         |
| „ „ Fæces - - - - -        | 2.56         | 2.61               | 2.59          | 1.96          |
| Balance - - - - -          | +35.03       | +37.93             | +38.27        | +41.35        |
| Assimilation % - - - - -   | 93.19        | 93.57              | 93.66         | 95.47         |
| „ in dry Fæces % - - - - - | 17.2         | 23.3               | 19.0          | 14.7          |

From the figures in this table it will be seen that the same remarks apply as in Observation I., viz., that boric acid and borax exerted no influence upon fat metabolism.

The remaining points to be considered may, as in the preceding observation, be divided as follows :—

Appendix.

The *quantity of urine* was decidedly diminished during the borax period, to a less extent during the boric acid period. The specific gravity increased with the diminishing volume. The reaction of the urine kept constantly acid to litmus during both the boric acid and borax period. In the fore period it varied between amphoteric and acid.

*Quantity of faeces.*—During the boric acid period the quantity of faeces was slightly decreased.

The *uric acid* variation is too slight to permit of any conclusion being drawn from it. The alteration in the quantity of total *sulphuric acid* during the respective periods was very slight, but in the same direction as that of the total nitrogen. The *etheral sulphates* underwent no change during the boric acid period, but increased slightly during the borax period. Neither substance exerted therefore any intestinal antiseptic action, the increase during the borax period is probably an alkali effect, the same having been observed in the case of other alkaline salts. Boric acid showed itself in the urine of the first day of its administration, and disappeared completely in the course of the second day of the after period.

The *body weight* increased during the boric acid and borax periods.

The results relevant to the observations made above are summarised in the following table :—

TABLE IIIA.

\* As in Table II.a.

\*\* " " "

### Observation III. Child C.

The child was a delicate girl, aged four years, weighing 15.6 kilos. She was convalescent from pneumonia and compared with the other children not so well nourished or developed. She consumed daily 200 g. of bread, 550 cc. of milk, 20 g. of butter, 30 g. of meat, 50 g. of apple compote, 10 g. of sugar, 50 cc. of water, 5 g. of toffee.

The whole observation lasted for twenty-two days, of which five days were devoted to the fore period, seven days to boric acid, five days to borax, and five days to the after period.

The boric acid and borax were administered as shown in the following table :—

#### Boric Acid Period.

3 days : 0.5 g. per diem = 1 : 1000 in milk = 1 : 1800 in total food and drink.

3 days : 0.66 g. " = 1 : 760 " = 1 : 1370 " " "

1 day : 1.0 g. " = 1 : 500 " = 1 : 330 " " "

#### Borax Period.

5 days : 1.5 g. per diem = 1 : 330 in milk = 1 : 600 in total food and drink.

It may be noted that the maximum medicinal dose for this child is in the case of boric acid 0.24 g., of borax 0.33 g., and that the quantities given, as in the former observations, are greatly in excess of those which would be required as a food preservative.

The analytical results obtained throughout this observation are recorded in the following table :—

## Appendix.

TABLE IV.

## Appendix

The results expressed in the above table are represented graphically in the following curves :—

Curve V.

Showing the influence of boric acid and borax upon the nitrogen and phosphorous metabolism of an invalid child.

Curve VI.

Showing the influence of boric acid and borax upon the fat assimilation, and upon the quantity of faeces and urine of an invalid child.

Adopting the same method as in the previous observations we arrive at the following results with regard to

Appendix.

*Nitrogen Metabolism.*

|                             | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-----------------------------|--------------|--------------------|---------------|---------------|
| Nitrogen in Food - - - - -  | 6.87         | 6.29               | 6.22          | 6.32          |
| „ „ Urine - - - - -         | 5.52         | 5.01               | 4.70          | 5.20          |
| „ „ Faeces - - - - -        | 0.72         | 0.65               | 0.75          | 0.72          |
| Balance - - - - -           | +0.62        | +0.62              | +0.77         | +0.39         |
| Assimilation % - - - - -    | 89.52        | 89.66              | 87.94         | 88.61         |
| „ in dry Faeces % - - - - - | 6.3          | 5.6                | 6.4           | 7.0           |

The assimilation of proteids was in this case not affected by boric acid, but slightly decreased by borax. The balance remained practically constant, being near the equilibrium.

In this case boric acid does not seem to have stimulated proteid katabolism, whilst borax showed its usual inhibitory tendency.

*Phosphorus Metabolism.*

|                                      | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|--------------------------------------|--------------|--------------------|---------------|---------------|
| Phosphorus in Food - - - - -         | 0.78         | 0.80               | 0.81          | 0.80          |
| „ „ Urine - - - - -                  | 0.4399       | 0.4186             | 0.4168        | 0.4619        |
| „ „ Faeces - - - - -                 | 0.2772       | 0.2406             | 0.2655        | 0.2410        |
| Balance - - - - -                    | +0.06        | +0.14              | +0.13         | +0.10         |
| Assimilation % - - - - -             | 64.46        | 70.00              | 67.23         | 69.88         |
| Phosphorus in dry Faeces % - - - - - | 2.4          | 2.1                | 2.1           | 2.3           |

As in the former cases the phosphorus assimilation was improved, especially in the boric acid period. The katabolism of substances rich in phosphorus seemed to be slightly inhibited in both periods.

*Fat Metabolism.*

|                               | Fore Period. | Boric Acid Period. | Borax Period. | After Period. |
|-------------------------------|--------------|--------------------|---------------|---------------|
| Fat in Food - - - - -         | 35.50        | 37.16              | 39.00         | 41.68         |
| „ „ Faeces - - - - -          | 2.35         | 2.44               | 2.48          | 1.80          |
| Balance - - - - -             | +33.14       | +34.71             | +36.51        | +39.88        |
| Assimilation % - - - - -      | 93.38        | 93.43              | 93.64         | 95.68         |
| Fat in dry Faeces % - - - - - | 20.6         | 20.8               | 21.2          | 17.8          |

As in the former cases the fat balance increased with the amount of fat ingested. The assimilation of fat was not affected.

The remaining points to be considered may, as in the preceding observations, be classified as follows :—

The quantity of urine decreased during the boric acid and borax period to the same extent, the specific gravity increasing with the diminishing volume. The reaction varied between acid and amphoteric during the boric acid period, and remained acid throughout the borax period.

The quantity of dry faeces underwent no change during the boric acid and borax period.

The uric acid excretion decreased somewhat during the boric acid period along with the decrease of nitrogen in food and the decreased nitrogen excretion in urine. During the borax period, however, we observed an increase in the amount of uric acid excreted, although the total nitrogen in the food and urine diminished. This seems to point to a specific uric acid solvent effect on the part of the borax, and not to an increased uric acid formation, as in the after period the uric acid sank considerably below the fore period level.

The somewhat decreased quantity of total sulphuric acid excreted during the borax period confirms the

Appendix. conclusion drawn from the decreased nitrogen and phosphorus—namely, that borax tends to slightly inhibit katabolism.

As in the former case, neither substance exerted an intestinal antiseptic action, borax, probably by virtue of its alkalinity, tending to increase the amount of ethereal sulphates eliminated.

Boric acid could be demonstrated in the urine in the first day of its administration, and was completely absent on the second day of the after period.

The body weight increased during both boric acid and borax period.

The results relevant to the observations made above are summarised in the following table:—

TABLE IVa.

|                       | Nitrogen<br>Assimilation<br>% | % N<br>of dry<br>Fæces. | Phosphorus<br>Assimilation<br>% | % P<br>of dry<br>Fæces. | Fat<br>Assimilation<br>% | % Fat<br>of dry<br>Fæces. | $\frac{A}{B}$ * | $\frac{N}{SO_3}$ ** |

$$\left. \begin{array}{l} * \frac{A}{B} \\ ** \frac{N}{SO_3} \end{array} \right\} \text{as in tube IIIa.}$$

In all the three observations we estimated the amount of *lecithin* in the fæces during the normal and drug periods. The result of these investigations together with others will form the subject of a future paper, and we will restrict ourselves here to the simple statement that the excretion of *lecithin* with the fæces was diminished in each case during the borax periods. This observation, together with the fact of the improved phosphorus assimilation seems to point to a stimulating effect of this drug upon the pancreatic digestion, thus corroborating "in vitro" what has already been shown "in vitro." (Compare Chittenden, loc. cit.)

Before proceeding to draw our general conclusions we give for the sake of reference, in our diagram, the result of the three observations expressed graphically, in so far as regards the influence of boric acid and borax upon nitrogen, phosphorus, and fat assimilation and body-weight.

Curve VII.

Showing the influence of boric acid and borax upon the body weight, and upon the nitrogen, phosphorus, and fat assimilation of three children.

Child A.

Child B.

Child C.

## Appendix.

*General Conclusions.**Boric Acid.*

- (1.) Small doses up to 1 gramme per diem, continued for some time, exert, in healthy or delicate children, no influence upon proteid metabolism. The assimilation of the proteid food was improved in one healthy child (*B.*)
- (2.) The phosphorus metabolism was unaffected in all cases. The assimilation of phosphorus was in all cases improved.
- (3.) The assimilation of fat was not affected.
- (4.) The body weight increased in all cases.
- (5.) The quantity of dry fæces was not affected. Their nitrogen and phosphorus percentage was slightly decreased.
- (6.) No inhibitory effect upon intestinal putrefaction could be demonstrated.

*Borax.*

- (1.) Continued doses of 1.5 grammes have no influence in healthy or delicate children upon proteid metabolism. The proteid assimilation was unaffected in healthy children, slightly depressed in the delicate child.
- (2.) The phosphorus metabolism was not affected in healthy or delicate children. The assimilation of phosphorus was improved in all cases, the improvement being least marked in the case of the delicate child.
- (3.) The fat assimilation was improved in the case of one healthy child, and unaffected in the case of the others.
- (4.) The body-weight was increased in all cases, the increase was most marked in the case of the delicate child.
- (5.) The weight of dry fæces and their nitrogen and phosphorus percentage remained unaltered.
- (6.) Borax tended rather to increase intestinal putrefaction.

*Boric Acid and Borax.*

- (1.) Both boric acid and borax were quickly eliminated, no cumulative action being therefore probable.
- (2.) Neither boric acid nor borax in any way affected the general health and well-being of the children.

If we compare these results with those obtained in the only previous complete observation made by Forster (*loc. cit.*) on the action of boric acid upon the general metabolism of one adult man, we find that they are only in accord in so far as in neither could any material effect upon the general health and metabolism be observed. In none of our three cases, however, could we confirm Forster's single observation that boric acid caused an increase in the quantity of fæces and in their nitrogen and phosphorus percentage. Further, in contradistinction to Forster, we were unable to find that boric acid exerted any inhibitory effect on intestinal putrefactive action.

If, on the other hand, we compare our results upon children with those obtained by Chittenden and Gies (*loc. cit.*) with similar doses of these substances upon the metabolism of dogs, it will be seen that in the essential points they agree.

---

## APPENDIX No. VIII.

TABLES, COMPILED UNDER THE DIRECTION OF PROFESSOR THORPE, GIVING THE RESULTS OF ANALYSES OF SAMPLES OF FOOD AND DRINK MADE IN THE GOVERNMENT LABORATORY, IN RELATION TO CONTAINED PRESERVATIVES AND COLOURING MATTERS.

TABLE A.

SHOWING the NUMBER of SAMPLES of IMPORTED PRODUCE Examined in the GOVERNMENT LABORATORY, and the PRESERVATIVES found therein.

| No. | Description.                                                               | Total Number of Samples. | Preservatives. |                 |            | Total containing Preservatives. | Percentage Preserved. |
|-----|----------------------------------------------------------------------------|--------------------------|----------------|-----------------|------------|---------------------------------|-----------------------|
|     |                                                                            |                          | Boric Acid.    | Salicylic Acid. | Sulphites. |                                 |                       |
| 1   | Ham - - - - -                                                              | 62                       | 58             | —               | —          | 58                              | 93·5                  |

| Percentage - - - - -                     | —               | 53·8                 | 18         | 10        |

The preservative (exclusive of salt) was in all cases a boron compound.  
 The vegetable yellow used for colouring was invariably annatto, and the coal-tar colour employed gave in nearly every instance the reaction of "butter-yellow" (dimethylamido-azo-benzene).

*N.B.*—The above percentages may be converted into *grains per pound* in the case of Butter by multiplying by 70, and by 87·5 to convert percentages of Boric Acid in Milk and Cream into *grains per pint*.

The highest amounts were found in Samples from London Hospital.

## Appendix.

TABLE H.  
PRESERVATIVES supplied by MANUFACTURERS and other TRADERS.  
(A.) BORIC PRESERVATIVES.

The figures in ordinary type express *Percentages*, and those in *Italics* *Grains Per Pint* of Liquid Foods and *Per Pound* of Solid Foods. The figures in bold type express *Percentages*, and those in *Italics* *Grains Per Pint* of Liquid Foods and *Per Pound* of Solid Foods. N.B.—it will be observed that in this Table the Percentage of the active ingredient often slightly exceeds 100. This is due to the fact that the whole of the boric preservative has been calculated in the usual manner as Boracic Acid—B (HO<sub>2</sub>)—whether present as Boracic Acid, Borax, or other form of Borates. The effect of expressing Anhydrous Borax, for example, as Boracic Acid, is to increase the percentage in the ratio 50·5 to 62·0. The amount of Anhydrous Borax actually present varied between the limits 3·8 per cent. and 24·9 per cent., the average amount being 10 per cent.

| Pro-<br>gressive<br>Number. | Price<br>per<br>lb. | Amount of the active Preservative Ingredient recommended by the Trader (as per directions for use) expressed in Percentages, and in Grains Per Pint for Liquid, and in Grains Per Pound for Solid Foods. |       |        |                             |                                               |                                                              |                       |                                                             |                      |                                       | Percentage of the Active Preservative Ingredients found on Analysis. |                 |                |                    |                    |                                 |   |                                                                                                                                      | OBSERVATIONS. |

## (C.) THE following consisted of various kinds of SALT.

| Progressive<br>Number. | Name of Preservative.      | Percentage of Salt<br>as NaCl. | Observations by Trader.                                                                                                              |
|------------------------|----------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 40                     | Dairy salt - - - -         | 99·5                           | —                                                                                                                                    |
| 41                     | Dairy salt - - - -         | 98·3                           | For butter and cheese, 3 per cent. suffices to keep<br>butter for more than six months.                                              |
| 42                     | Curer's or packer's salt - | 98·9                           | The best kind for pork packing or bacon curing ; also<br>used on the Pacific Coast for salmon and lobster<br>tinning.                |
| 43                     | Fishery salt (No. 1) - -   | 92·4                           | For Scotch and Yarmouth herring and Irish mackerel<br>fisheries (150 lbs. in 400 lb. barrel of fish).                                |
| 44                     | Fishery salt (No. 2) - -   | 95·3                           | A better quality than No. 43, as it is free from iron<br>impurity.                                                                   |
| 45                     | Coarse common salt - -     | 97·7                           | Used for general purposes by curers and packers in<br>the United Kingdom as more adapted for use in<br>our damp climate than No. 42. |

## (D.) "MISCELLANEOUS" PRESERVATIVES.

| Progressive<br>Number. | Name of Preservative.                 | Use, &c.                                                                                             |
|------------------------|---------------------------------------|------------------------------------------------------------------------------------------------------|
| 46                     | Egg preservative - - -                | The eggs are kept in the solution, which contains,<br>approximately, 1 per cent. of sodium silicate. |
| 47                     | Beta-naphthol. Sulphonate<br>of soda. | Supplied by the "Sal Preservare" Company, and<br>said to be used on the continent.                   |

TABLE J.

## SOME QUANTITATIVE DETERMINATIONS of the Amount of Preservatives in Foods Examined in the GOVERNMENT LABORATORY.

## (A.)—Boric Preservative.

For the following estimations of the amount of boric acid those samples were selected (with the exception of the hospital samples, all of which were examined) which indicated on preliminary qualitative examination, a relatively large amount of the preservative.

## (a.) Milks. (14 samples examined.)

|         |   |   |   |   |   |   |                            |   |                      |
|---------|---|---|---|---|---|---|----------------------------|---|----------------------|
| Maximum | - | - | - | - | - | - | 104 per cent. as $B(HO)_3$ | = | 9.1 grains per pint. |
| Minimum | - | - | - | - | - | - | 0.15                       | " | = 1.3 "              |
| Average | - | - | - | - | - | - | 0.62                       | " | = 5.4 "              |

## (b.) Creams. (9 examples examined.)

|         |   |   |   |   |   |   |                            |   |                     |
|---------|---|---|---|---|---|---|----------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 651 per cent. as $B(HO)_3$ | = | 57 grains per pint. |
| Minimum | - | - | - | - | - | - | 114                        | " | = 10 "              |
| Average | - | - | - | - | - | - | 366                        | " | = 32 "              |

## (c.) Sausages, Potted Meats and Brawn. (11 samples examined.)

|         |   |   |   |   |   |   |                            |   |                   |
|---------|---|---|---|---|---|---|----------------------------|---|-------------------|
| Maximum | - | - | - | - | - | - | 943 per cent. as $B(HO)_3$ | = | 66 grains per lb. |
| Minimum | - | - | - | - | - | - | 217                        | " | = 15 "            |
| Average | - | - | - | - | - | - | 477                        | " | = 33 "            |

## (d.) Butters. (10 samples examined.)

|         |   |   |   |   |   |   |                            |   |                     |
|---------|---|---|---|---|---|---|----------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 935 per cent. as $B(HO)_3$ | = | 65.5 grains per lb. |
| Minimum | - | - | - | - | - | - | 264                        | " | = 18.5 "            |
| Average | - | - | - | - | - | - | 477                        | " | = 33.3 "            |

## (e.) Margarines. (8 samples examined.)

|         |   |   |   |   |   |   |                            |   |                     |
|---------|---|---|---|---|---|---|----------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 105 per cent. as $B(HO)_3$ | = | 73.5 grains per lb. |
| Minimum | - | - | - | - | - | - | 0.10                       | " | = 7 "               |
| Average | - | - | - | - | - | - | 0.43                       | " | = 30 "              |

## (f.) Bacon. (10 samples examined.)

|         |   |   |   |   |   |   |                            |   |                     |
|---------|---|---|---|---|---|---|----------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 661 per cent. as $B(HO)_3$ | = | 46.3 grains per lb. |
| Minimum | - | - | - | - | - | - | 123                        | " | = 8.6 "             |
| Average | - | - | - | - | - | - | 329                        | " | = 23.0 "            |

## (g.) Temperance Beverages.

## (1.) Temperance wines and cordials. (Nil.)

## (2.) Herb beers and similar temperance drinks. (8 samples.)

|         |   |   |   |   |   |   |                            |   |                      |
|---------|---|---|---|---|---|---|----------------------------|---|----------------------|
| Maximum | - | - | - | - | - | - | 083 per cent. as $B(HO)_3$ | = | 7.3 grains per pint. |
| Minimum | - | - | - | - | - | - | 013                        | " | = 1.2 "              |
| Average | - | - | - | - | - | - | 043                        | " | = 3.8 "              |

## (h.) Hospital samples.

## (1.) Butter. (83 samples.)

|         |   |   |   |   |   |   |                           |   |                     |
|---------|---|---|---|---|---|---|---------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 91 per cent. as $B(HO)_3$ | = | 63.7 grains per lb. |
| Minimum | - | - | - | - | - | - | 10                        | " | = 70 "              |
| Average | - | - | - | - | - | - | 432                       | " | = 30.2 "            |

## (2.) Cream. (7 samples from St. George's and St. Mary's only.)

|         |   |   |   |   |   |   |                           |   |                     |
|---------|---|---|---|---|---|---|---------------------------|---|---------------------|
| Maximum | - | - | - | - | - | - | 41 per cent. as $B(HO)_3$ | = | 36 grains per pint. |
| Minimum | - | - | - | - | - | - | 17                        | " | = 15 "              |
| Average | - | - | - | - | - | - | 268                       | " | = 23.5 "            |

## (3.) Milk. (3 samples from St. George's only.)

|         |   |   |   |   |   |   |                           |   |                       |
|---------|---|---|---|---|---|---|---------------------------|---|-----------------------|
| Maximum | - | - | - | - | - | - | 20 per cent. as $B(HO)_3$ | = | 17.5 grains per pint. |
| Minimum | - | - | - | - | - | - | 03                        | " | = 2.6 "               |
| Average | - | - | - | - | - | - | 086                       | " | = 7.5 "               |

## (B.)—Salicylic Preservative. (As Salicylic Acid.)

## (a.) Jams. (13 samples taken indiscriminately.)

|         |   |   |   |   |   |   |   |   |   |                                    |
|---------|---|---|---|---|---|---|---|---|---|------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 121 per cent. = 8.5 grains per lb. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.24 " = 1.7 "                     |
| Average | - | - | - | - | - | - | - | - | - | 0.55 " = 3.8 "                     |

## (b.) Temperance Drinks.

## (1.) Temperance wines and cordials. (10 samples examined.)

|         |   |   |   |   |   |   |   |   |   |                                    |
|---------|---|---|---|---|---|---|---|---|---|------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 22 per cent. = 19 grains per pint. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.17 " = 1.5 "                     |
| Average | - | - | - | - | - | - | - | - | - | 1.03 " = 9 "                       |

## (2.) Herb beers and similar beverages. (25 samples.)

|         |   |   |   |   |   |   |   |   |   |                                       |
|---------|---|---|---|---|---|---|---|---|---|---------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 0.93 per cent. = 8.1 grains per pint. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.06 " = 0.5 "                        |
| Average | - | - | - | - | - | - | - | - | - | 0.30 " = 2.6 "                        |

## (c.) Imported Beers. (19 samples.)

|         |   |   |   |   |   |   |   |   |   |                                       |
|---------|---|---|---|---|---|---|---|---|---|---------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 0.39 per cent. = 3.4 grains per pint. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.15 " = 1.3 "                        |
| Average | - | - | - | - | - | - | - | - | - | 0.25 " = 2.1 "                        |

## (C.)—Sulphites. (Estimated as sulphur di-oxide.)

## (a.) Temperance Drinks. (Lime juice, ginger wine, lemon syrup, raspberry cordial and peppermint.) (13 samples examined.)

|         |   |   |   |   |   |   |   |   |   |                                                            |
|---------|---|---|---|---|---|---|---|---|---|------------------------------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 0.52 per cent. as (SO) <sub>2</sub> = 4.5 grains per pint. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.01 " = 0.1 "                                             |
| Average | - | - | - | - | - | - | - | - | - | 0.21 " = 1.8 "                                             |

## (b.) Imported Beers. (20 samples examined by Customs.)

|         |   |   |   |   |   |   |   |   |   |                                                             |
|---------|---|---|---|---|---|---|---|---|---|-------------------------------------------------------------|
| Maximum | - | - | - | - | - | - | - | - | - | 0.018 per cent. as (SO) <sub>2</sub> = 1.6 grains per pint. |
| Minimum | - | - | - | - | - | - | - | - | - | 0.002 " = 0.2 "                                             |
| Average | - | - | - | - | - | - | - | - | - | 0.008 " = 0.7 "                                             |

## (D.)—Formalin.

|       |   |   |   |   |   |   |   |   |   |                                  |

## Appendix.

TABLE P.

LIST of COLOURING MATTERS used in CONFECTIONERY, from Mr. L. K. BOSELEY  
(KEILLER & SON, SILVERTOWN).

| Number. | Trade Names.                   | Colours.        | Scientific Names.                                                     |
|---------|--------------------------------|-----------------|-----------------------------------------------------------------------|
| 1       | French Cream Pink (Rhodamine). | Reds            | Hydrochlorate of the phthalein of di-ethyl-meta-amido-phenol.         |
| 2       | Concentrated Pink              |                 | A mixture of hydrochlorate of rosaniline with milk, sugar, or starch. |
| 3       | Magenta                        |                 | Fuchsin, hydrochlorate or acetate of rosaniline.                      |
| 4       | Rhodites                       |                 | Hydrochlorate of phthalein of di-ethyl-meta-amido-phenol.             |
| 5       | Cherry Red                     |                 | Sodium salt of tetra-iod-fluorescein.                                 |
| 6       | Ponceau Red                    |                 | Biebrich or Crocein scarlet. Sodium-benzene-naphthol-sulphonic acid.  |
| 7       | Vermilion                      |                 | A pure aniline colour.                                                |
| 8       | Rose Red                       |                 | Purified aniline colour. Guaranteed harmless.                         |
| 9       | Saffron Yellow                 | Yellows, &c     | Probably the sodium salt of amido-azo-benzene sulphonic acid.         |
| 10      | Primrose Yellow                |                 | Auramine. (This colour is sold in three grades, 1, 2, and 0).         |
| 11      | Imperial Yellow                |                 | Ammonium or sodium salt of hexanitrodiphenyl-amine.                   |
| 12      | Citron Orange                  | Brown and Black | The sodium salt of xylene-sulphonic-acid-azo-B-naphthol.              |
| 13      | Chocolate Brown                |                 | An aniline colour. (No details as to composition).                    |
| 14      | Jetoline Black                 | Violets         | Probably di-amine black.                                              |
| 15      | Heliotrope                     |                 | Hoffman's violet R., hydrochlorate of tri-ethyl rosaniline.           |
| 16      | Lavender                       |                 | A mixture of Hoffman's violet.                                        |
| 17      | Damson Blue                    |                 | Also a mixture of Hoffman's violet.                                   |

The following colours are also used. (Scientific names not given). Rose paste, brown paste, Tuscan, orange, and salmon pink. The first two are probably mixtures of some of the above named colours, with aluminium hydroxide.

TABLE Q.

CONFECTIONERY COLOURED ARTIFICIALLY. SENT by MR. L. K. BOSELEY (KEILLER &amp; SON, SILVERTOWN).

|                       |                                                  |                                                          |
|-----------------------|--------------------------------------------------|----------------------------------------------------------|
| Fondants              | Cream pink (rose)                                |                                                          |
|                       | Imperial yellow (pale cold yellow).              |                                                          |
|                       | Heliotrope (very pale lavender).                 |                                                          |
|                       | Mixture of 1 and 2.                              |                                                          |
| Mixed bouquet cachous | Lemon yellow and real saffron (yellow)           | 1 in 23,000 to 1 in 5,000<br>(.004 to .02 per cent.)     |
|                       | Rhodime and raspberry red (decided rose red).    |                                                          |
|                       | „ heliotrope (purple).                           |                                                          |
|                       | Jetoline black and heliotrope (slate colour).    |                                                          |
|                       | Citron Orange (pale orange).                     |                                                          |
|                       | Heliotrope (lilac colour).                       |                                                          |
| Oriental beans        | Rose pink (crimson)                              | 1 in 3,500 to 1 in 1,000<br>(.028 to 0.1 per cent.)      |
|                       | Lemon yellow (greenish yellow).                  |                                                          |
|                       | Citron orange (only just perceptible).           |                                                          |
|                       | Chocolate brown (reddish brown).                 |                                                          |
|                       | Jetoline black (slaty black).                    |                                                          |
| Sugar boilings        | Rose pink (pale and dark rose)                   | 1 in 5,500 to 1 in 2,500<br>(.018 to .04 per cent.)      |
|                       | „ and Jetoline black (reddish brown).            |                                                          |
|                       | Vegetable yellow (pale yellow).                  |                                                          |
|                       | Citron orange (pale and dark orange).            |                                                          |
|                       | Chocolate brown and jetoline black (dark brown). |                                                          |
| Fruit jujubes         | Red with cochineal                               |                                                          |
|                       | Yellow with apricot (real) (orange yellow).      |                                                          |
|                       | Green (with liquid blue colour).                 |                                                          |
| Gum jujubes           | Rose pink (decided red)                          | 1 in 5,500<br>(.018 per cent.)                           |
|                       | Citron orange (orange).                          |                                                          |
|                       | Lemon yellow (very slight yellow).               |                                                          |
|                       | Damson blue (bluish violet).                     |                                                          |
| Cachous               | (a) Rhodamine (pink)                             | 1 in 23,000<br>(.004 per cent.)                          |
|                       | (b) Heliotrope (reddish violet)                  | 1 in 7,500<br>(.013 per cent.)                           |
|                       | (c) Lavender (bluish violet)                     | 1 in 5,000<br>(.02 per cent.)                            |
| Lozenges              | Rhodamine (pale pink to deep rose)               | 1 in 30,000 to 1 in 2,340<br>(.003 to .0428 per cent.)   |
|                       | Lemon yellow (pale cold yellow).                 |                                                          |
| Gelatin jujubes       | Rose pink                                        | 1 in 5,500<br>(.018 per cent.)                           |
|                       | „ and black currant (purplish red).              |                                                          |
|                       | „ and orange (reddish orange).                   |                                                          |
|                       | „ and damson blue (dark violet).                 |                                                          |
|                       | Citron orange (decided orange).                  |                                                          |
| Cupid lozenges        | Concentrated pink                                | 1 in 33,000 to 1 in 17,000<br>(.003 to .00588 per cent.) |
|                       | Cream pink.                                      |                                                          |
|                       | Lemon yellow.                                    |                                                          |
|                       | Lavender.                                        |                                                          |
| Buttons               | Citron orange.                                   |                                                          |
|                       | Concentrated pink                                |                                                          |
|                       | Cream pink.                                      |                                                          |
|                       | Lemon yellow.                                    |                                                          |
|                       | Chocolate brown.                                 |                                                          |
|                       | Lavender.                                        |                                                          |
|                       |                                                  | Same proportions as last group.                          |

## Appendix.

TABLE R.

MAXIMUM AMOUNTS of COLOURING MATTERS found in FOODS by various observers.

| Kind of Food, &c.                 | Colouring Matter.     | Amount of Colouring Matter.       | Authority.                |
|-----------------------------------|-----------------------|-----------------------------------|---------------------------|
| Preserved Vegetables (Peas, &c.). | Copper sulphate (a) - | 094 per cent. = 6.6 grs. per lb.  | "Sanitary Record" (1897). |
| - do. - do. -                     | - do. - - -           | 022 ,, 1.5 ,,                     | Mr. Vasey.                |
| - do. - do. -                     | - do. - - -           | 016 ,, 1.1 ,,                     | Professor A. W. Blyth.    |
| - do. - do. -                     | - do. - - -           | 010 ,, 0.7 ,,                     | Mr. W. F. Lowe.           |
| - do. - do. -                     | - do. - - -           | 010 ,, 0.7 ,,                     | M. Riche (Paris).         |
| - do. - do. -                     | - do. - - -           | 0085 ,, 0.6 ,,                    | Mr. Cassal.               |
| Piccalilli - - -                  | Turmeric - - -        | 4 lbs. to 40 gallon barrel -      | Mr. L. K. Boseley.        |
| Pickled Cabbage - -               | Sulphuric acid (b) -  | - do. - do. -                     | - ditto.                  |
| Milk - - - -                      | Annatto - - -         | 1 in 300,000. - - -               | - ditto.                  |
| Sweets - - - -                    | Oxide of Iron - -     | 0.4 per cent. = 28 grs. per lb. - | Mr. Cassal.               |
| Bloater Paste - - -               | - do. - - -           | 0.34 ,, 24 ,,                     | Mr. Fisher.               |

(a) In the evidence, the copper colouring matter is variously described as "copper," "copper sulphate" or "crystallised copper sulphate," but the figures in the above table are in all cases expressed in terms of *metallic* copper.

The above figures multiplied by four will give approximately the amount expressed as crystallised sulphate of copper.

(b) Sulphuric acid, though not itself a colouring matter, has the property (common to acids generally) of acting on pickled cabbage so as to produce a bright red colour.

## APPENDIX No. IX.

## RAILWAY TRANSPORT OF MILK AND BUTTER IN ENGLAND.

With a view to secure information from the chief railway companies having termini in London, and whose lines traverse the milk and butter producing counties of England, the following letter was sent to nine companies, namely:—The Great Central, Great Eastern, Great Northern, Great Western, London, Brighton, and South Coast, London and North-Western, London and South-Western, Midland, and South-Eastern and Chatham Railway Companies:—

Local Government Board, Whitehall, S.W.,  
5th October, 1900.

Dear Sir,

The Food Preservatives Committee, appointed by the President of this Board, have found occasion during the progress of their investigations to make inquiry concerning methods of transport by land and water as regards parts of the Continent and Ireland, and they are desirous of having information from the great railway companies of England concerning the facilities granted for the carriage, especially, of milk and butter.

The Committee will therefore be very glad if you will kindly furnish them with information on the following points as regards your railway system, and upon any other matters which seem to you to be pertinent to the inquiry in question.

(1) Are any special trucks set apart for the conveyance of milk or butter?

(2) Are these commodities sent alone or in conjunction with other articles, and, if so, what?

(3) Is milk or butter sent in refrigerating cars or in ice-wagons?

(4) If not, have the wagons used for such produce double walls and roofs and any special methods of ventilation?

(5) Do milk and butter go by passenger or goods trains?

(6) Are any special precautions taken to keep trucks so used in the shade during the heat of summer while awaiting their cargoes at provincial stations?

(7) What are the maximum distances in one and another direction from which milk and butter are carried, and how many hours are occupied in the journey to London?

(8) Is the milk and butter traffic on your railway extensive, and have any complaints been received as to damage of produce in transport?

Trusting that you will be good enough to furnish information on the above several points for the purposes of the Committee.

I am, yours faithfully,

(Signed) CHAS. J. HUDDART,  
Secretary to the Committee.

The Traffic Superintendent,  
——— Railway Company.

The following replies have been received:—

## GREAT CENTRAL RAILWAY.

I beg to give you the information so far as this company is concerned:—

(1) We have a large traffic in butter and margarine, for which special vehicles are provided.

(2) About 90 per cent. of the traffic is conveyed alone. The other 10 per cent. is carried with general merchandise.

(3) We have neither refrigerator cars nor ice-wagons.

(4) The special vehicles are built in the ordinary way, but with ventilated sides (louvred), but protected on the inside with perforated zinc. They are also fitted with four Torpedo ventilators in the roof.

(5) Butter is chiefly conveyed by special butter trains.

(6) No special precautions are taken to keep trucks so used in the shade in summer.

(7) The greater proportion of our butter traffic passes between Grimsby Docks and Manchester, distance 100

miles, the usual time occupied by the special trains conveying same being about four hours. We have no butter traffic to London.

(8) The butter and margarine traffic is extensive, some 10,000 packages being received at Grimsby weekly. Considering the weight of the traffic and the nature of same the complaints are very small, and not more than the average for general merchandise.

WILLIAM POLLITT,  
General Manager.

7th November, 1900.

## GREAT EASTERN RAILWAY.

The quantity of butter produced in our district is comparatively small, and is usually sent packed with other commodities of farm produce for home consumption under the arrangement referred to in the enclosed pamphlet.\*

(1) Yes, on certain trains for milk.

(2) Milk sent alone; butter usually in small consignments, as previously stated.

(3) No.

(4) For the conveyance of milk: the vans are specially constructed for the purpose, and ventilated with louvres at the sides.

(5) Principally by passenger train.

(6) As far as circumstances will permit.

(7) About 130 miles; the time occupied on the journey being approximately four hours.

(8) During 1899 we conveyed, without complaints of damage in transport, about 580,000 cans containing about 7,000,000 Imperial gallons of milk.

H. G. DRURY,  
Superintendent of the Line.

11th October, 1900.

## GREAT NORTHERN RAILWAY.

I give you below the particulars asked for:—

(1) Special vehicles are set apart for the conveyance of milk by passenger or special train from the milk-producing districts of Nottinghamshire, Derbyshire, and Staffordshire, but not for butter, which is conveyed in the guard's van by passenger train and in goods wagons by goods train.

(2) Milk from the above-mentioned districts is usually sent in special trains, but when only small quantities are forwarded it is carried with the ordinary parcels traffic in the guard's van. Milk is not conveyed by goods trains.

(3) and (4) Refrigerating vans are not provided for milk and butter on the Great Northern Railway, nor have vehicles provided for such produce double walls and roofs. They are, however, well ventilated. When practicable, refrigerator vans are used for the conveyance of butter by goods train.

(5) Milk is conveyed by passenger or by special train, and butter by both passenger and goods trains.

(6) No special steps are taken for this purpose.

(7) The maximum distance milk is conveyed on the Great Northern Railway is about 150 miles, the time occupied being about five hours 25 minutes.

Butter is received in London in large quantities from Liverpool (200 miles), Newcastle (271 miles), and Grimsby (155 miles), and delivery is made the day after despatch. From these ports butter is sent all over the G.N. line.

(8) An extensive milk traffic comes from the Nottinghamshire, Derbyshire, and Staffordshire districts. The butter traffic from these districts is not extensive.

Complaints as to damage are very occasional.

J. ALEXANDER.

30th November, 1900.

## Appendix.

## GREAT WESTERN RAILWAY.

Concerning the facilities afforded for the conveyance of milk and butter over the Great Western Railway, I have pleasure in giving an answer in detail to each of the various questions contained in your communication:—

(1) Are any special trucks set apart for conveyance of milk or butter?—Milk is principally conveyed by passenger train, or by trains appointed for the exclusive purpose of conveying milk under passenger train conditions. The empty cans are worked in the same manner on the return journey. Milk is carried in passenger train vehicles, so constructed as to permit of an efficient draught of air through them, and at the same time afford shelter from the sun. The roofs of the vehicles are painted white. Moreover, with a view to the milk being carried by rail under the most favourable sanitary conditions, the vehicles used for its conveyance are retained as far as is practicable exclusively for the service. Butter when sent in large quantities is, where possible, carried in special vans, lined with zinc and with ventilators at each end. A very large proportion of this traffic, however, is forwarded by the traders in small lots, and is conveyed either in the vans used for merchandise traffic generally; or in some particular cases in vans with open sides and whitened roofs.

(2) Are these commodities sent alone or in conjunction with other articles, and if so, what?—By far the larger proportion of the milk traffic is conveyed separately from anything else. The exception is with odd cans and small lots, which generally travel in the guard's van. Butter, when forwarded in small quantities in boxes, tubs, baskets, crocks, cools, or hampers, is frequently loaded in wagons containing general merchandise.

(3) Is milk or butter sent in refrigerator cars or in ice wagons?—In England, milk is not generally conveyed in refrigerator cars, the distance being so short. On the Great Western Railway, the distance for which milk is carried would probably average about 60 miles. The vehicles are constructed as explained in answer to Question No. 1. Butter, in full loads, is carried in refrigerator cars so far as circumstances permit, or in the specially-constructed vans referred to in answer to Question No. 1. The refrigerator cars are fitted with ventilators and receptacles for ice. The major portion of the salted butter traffic is carried in the regulation merchandise vans.

(4) If not, have the wagons used for such produce double walls and roofs, and any special methods of ventilation?—The regulation merchandise van used by the company is stoutly built, but the walls and roofs are not double. The vans are sufficiently ventilated.

(5) Do milk and butter go by passenger or goods train?—Milk is carried almost entirely by passenger train, principally late at night, and early in the morning. Fresh butter is conveyed by passenger train or by goods train, as may be ordered by the trader; and salted butter nearly always travels by goods train.

(6) Are any special precautions taken to keep trucks so used in the shade during the heat of summer while awaiting their cargoes at provincial stations?—The point as regards the vehicles for the conveyance of milk is dealt with in answer to Questions No. 1. With regard to butter, the general custom is for it to be handled and dealt with under cover; and the vans intended for the conveyance of the traffic are placed in position in the roofed goods station or sheds as long as is practicable before the train time.

(7) What are the maximum distances in one and another direction from which milk and butter are conveyed, and how many hours are occupied in the journey to London?—Ninety-nine per cent. of the milk traffic received in London by Great Western Railway is from stations within 150 miles distant, and the time occupied in its conveyance for the full distance might be about six hours. It is explained, in answer to Question No. 3, that our average distance for conveying milk is about 60 miles, and the average time occupied would be about two hours. An important centre for milk forwarding to London is the Wiltshire Dairy district surrounding Swindon, a distance of 77 miles. This district is served by fast trains, appointed exclusively for the milk business, and the journey from Swindon to London by one of these trains occupies only 95

minutes. Milk is forwarded in small quantities for distances beyond 150 miles and up to about 300 miles, and the time occupied in the case of the longest journey would be about 11 hours. It has been found from experience that farmers and other senders of milk attach as much importance to the working of the returned empty cans, as they do to the conveyance of milk. This means in practice that every milk sending station must have its own service of milk vans or trucks independently of other stations, which necessitates the carriage of the returned empty churns being conducted by special trains or by passenger trains. At Paddington Station we have provided a line with approach road and extra platform exclusively for the accommodation of milk, and to keep it apart from the ordinary traffic. To illustrate the care taken in dealing with this branch of the company's business, one of the service orders regulating its working at the London stations is attached.\* The longest distance butter is conveyed by passenger train is from the South and West of Ireland to London, about 600 miles in all, and the time taken for its conveyance is about 24 hours. In addition, goods trains are used for salted butter from these districts, and the service to London occupies from 30 to 36 hours. Butter is also carried from the under-mentioned places by goods trains, and the approximate times occupied in transit are as shown below:—

| Station.       | Miles. | Approximate Train Journey. |
|----------------|--------|----------------------------|
| Penzance - - - | 327    | 16 hours.                  |
| Helston - - -  | 325    | 18 „                       |
| Redruth - - -  | 309    | 14 „                       |
| Penryn - - -   | 309    | 16 „                       |

(8) Is the milk and butter traffic on your railway extensive, and have any complaints been received as to damage of produce in transport?—The Great Western Company are the largest carriers of milk in the United Kingdom, the quantity conveyed by them during the year 1899 being as set out below:—

| No. of Cans. | No. of Gallons. |
|--------------|-----------------|
| 1,642,380    | 23,495,925.     |

The company are fully alive to the great importance of dealing with this business in a thoroughly smart and efficient manner, as will be illustrated by some of the earlier answers, and they spare no expense to give satisfaction and encouragement to the traders in milk. The result is that complaints of alleged damage to milk in transit have practically disappeared.

Some short time since it was represented to me by influential persons that the senders of milk were inconvenienced by certain of the branch lines of the company being closed on Sunday, which necessitated the supplies on that day being carted to the nearest main line station. With the desire of sympathetically dealing with every matter affecting the agriculturists of the districts served by the Great Western line, the question received careful consideration; and, as a result, Sunday trains by which milk is conveyed are in recent months being run upon the following branch lines in dairy districts.

Calne.  
Malmesbury.  
Highworth.  
Fairford.

It may be added that it has just been decided, with the same object, to extend the Sunday service on the Wells branch.

It may be mentioned that in the course of the proceedings on the Sale of Food and Drugs Bill in the early part of 1899, it was represented that hardship had arisen in connection with the prosecution of milk producers in cases where it had arisen that pure milk handed to a carrier for conveyance was suspected upon arrival at destination to have been adulterated.

It was further alleged that the railway companies required milk churns to be unlocked (except in cases where an additional charge for conveyance was made) a requirement which did not allow of precautions being taken to prevent persons from tampering with the milk whilst in charge of the company.

\* Not reproduced here.

These representations were placed before the railway companies for their observations, and in reply it was explained that a wrong impression existed so far as the railway arrangements were concerned, because as a matter of fact, the companies provide for and actually carry milk in sealed churns, the only condition being that the churns should have the tare weight stamped on the outside so that the declared contents might be checked by allowing 10½ lbs. for every gallon of milk.

Sealing is equivalent to locking, and it makes no difference to the railway companies whether the churns are sealed or locked; but, as the churns are never locked, it may be the dealers consider that, in practice, there would be a difficulty in arranging for the locking and unlocking of churns, which difficulty does not exist in the case of sealing.

About 400 sealed churns are received at Paddington daily, and I should be very glad to see the number largely increased, because there is good reason for believing that a certain amount of "blending" takes place. This practice may be beneficial for those consumers who would otherwise be supplied with the poor descriptions of milk; but it is not so satisfactory to those who desire to be supplied with the best milk that is procurable.

The butter traffic is extensive, being carried in considerable quantities from the South and West of England, and the South and West of Ireland to London; to the Midlands, and to the North of England. Imported butter is largely distributed from London, Bristol, and the other ports.

During very hot weather, complaints are sometimes received in regard to butter traffic, but every effort is made to avoid damage in transit, and the number of grievances is not large.

If, instead of farmers making up the butter on their own premises, they would combine, in each district, to establish a factory to which the milk could be sent for the purpose, this would not only enable the butter to be manufactured under better sanitary conditions, but would also allow of its being packed in such a manner, and sent in such quantities as would enable a through van to be run with it to destination, thereby ensuring its delivery in good condition. Could such a combination among the producers be brought about, the traffic could, no doubt, be handed to the railway companies at regular times and in reasonable quantities, in which event the Great Western Company would be quite prepared to make special arrangements for its conveyance on similar lines to those which exist in the case of milk traffic.

J. F. WILKINSON.

22nd November, 1900.

#### LONDON, BRIGHTON, AND SOUTH COAST RAILWAY. (Home Traffic.)

Your letter of the 14th inst. I regret I have been unable to send you an earlier reply, but trust that the following particulars will be of interest.

For the purpose of reference I have answered the questions in the order they occur in your communication:—

(1) Milk is carried on the platform of carriage trucks or in the luggage vans of passenger trains, according to the extent of accommodation required. Butter is usually carried in box vans or covered trucks. There is no demand for special trucks.

(2) Milk and butter are very rarely sent in conjunction.

(3) No.

(4) No.

(5) Milk only by passenger trains; butter by both services.

(6) Yes, when occasion requires, and the shade is available.

(7) The maximum distance between extreme points on the railway is only 86 miles, though the aggregate mileage is 487 miles. The time occupied on journeys may be a maximum of about 3½ hours by passenger train or about 10 hours by goods train.

(8) Milk traffic is fairly considerable; butter traffic of home produce very small. Few grounds of complaint arise as to damage in transport.

D. GREENWOOD.

19th April, 1901.

3017.

#### Continental Traffic.

Your favour of the 5th inst. addressed to the Traffic Superintendent, has been referred to me, as I understand your inquiry, so far as this company is concerned, is confined to foodstuffs from the Continent.

In the first place I would remark that we do not carry fresh milk from the Continent. We have been asked to do so on several occasions, but have declined in the interests of British producers.

We bring large quantities of Italian butter in boxes and baskets, which travel in through trucks from Italy to Dieppe, whence they are shipped to Newhaven, and then forwarded by rail to London, or to Brighton, Eastbourne, etc. This traffic is confined to the winter months.

We have also a service of steamers between Caen and Newhaven, and a considerable amount of Normandy butter travels by that route. This comes, in larger or smaller quantities, all the year round.

Although we have a few refrigerating vans, butters as a rule travel in ordinary trucks, box vans for preference.

We generally have sufficient butters to make up complete truck loads or if not we load with eggs.

The bulk of our butter being forwarded at "Petite Vitesse" rates, it is conveyed from Newhaven to London by goods trains, which generally travel by night.

I shall be pleased to furnish any further particulars which your Committee may desire.

J. W. WYLIE,

Continental Traffic Manager.

10th October, 1900.

#### LONDON AND NORTH WESTERN RAILWAY.

I beg to reply *seriatim* as follows to the eight questions embodied in your communication:—

(1) Special trucks are set apart for milk, but not for butter.

(2) Milk is largely sent alone, but in some cases with other articles. Butter generally with other articles.

(3) No.

(4) The wagons used have not double walls or roof, but they are specially ventilated.

(5) Milk goes by passenger trains, and butter to a large extent by goods trains.

(6) There are no special means of doing this.

(7) The longest distance milk is carried is from Tarff (Glasgow and South Western Railway) to Euston, which is handed to this company at Carlisle. The distance is 359 miles. As regards butter, that sent from Knocklong (G. S. and W. Railway) to Euston, via North Wall, represents the extreme point, the distance being 456 miles. The time occupied in the journey to London for the milk is about 8¼ hours, and for the butter 15½ hours.

(8) Very considerable traffic in milk and butter by passenger trains is conveyed on the London and North Western Company's line, and the complaints as to damage, etc., to milk and butter by passenger trains are very few.

F. HARRISON.

24th October, 1900.

#### LONDON AND SOUTH WESTERN RAILWAY.

With reference to your application concerning the methods of transport of milk and butter traffic, I beg to give below a few particulars as to this company's practice, and will deal with your questions in numerical order, viz.:—

(1) Special vans are provided for the conveyance of milk traffic, which are specially constructed so as to give plenty of ventilation, but butter traffic is generally conveyed in the guard's van, unless there is a sufficient quantity to warrant a special van being used, in which case it would be loaded into an ordinary closed van or a guard's van, whichever vehicle was available.

(2) Milk traffic is generally conveyed by special train, but in some cases churns are also conveyed by ordinary passenger trains; butter is conveyed by ordinary trains.

(3) We do not provide refrigerator vans or ice wagons for the conveyance of milk and butter traffic.

(4) Milk vans are not fitted with double walls, but they are well ventilated at the sides.

## Appendix.

(5) Milk traffic is not conveyed by goods train, but butter is sent by goods as well as passenger train.

(6) There is no accommodation at the majority of country stations, where vans can be placed under cover in the shade, and milk and butter traffic is usually loaded up either at a siding when a special truck is used, or at the platform after arrival of the trains, by which it is to be conveyed, and on arrival at Waterloo the milk churns are immediately unloaded and sent down a lift into the milk arch below, which is, of course, very cool, and butter traffic would be taken to the Parcels Office, and sent down the lift to the arch below to await delivery.

(7) The bulk of the milk traffic is drawn from the following stations, viz.:—Yeovil Junction, Sherborne, Milborne Port, Templecombe (including Somerset and Dorset Stations), Gillingham, Semley, Tisbury, Dinton, Wilton, Salisbury, and Porton, and the time occupied between Yeovil Junction and London by the milk train would be between 4 and 5 hours.

(8) The number of churns of milk which were dealt with at Vauxhall and Waterloo alone during the 12 months ending October 31st last was 511,170, and the traffic at Clapham Junction and other large stations is very great. We also have a very extensive traffic in farm and dairy produce, which is conveyed at special cheap rates. With regard to the question of complaints of damage I think that the number of complaints we receive is extremely small in proportion to the amount of traffic which is dealt with.

SAM FAY.

11th January, 1901.

## MIDLAND RAILWAY.

I have the pleasure to enclose herewith a statement answering *seriatim* the inquiries of the Food Preservatives Committee in regard to the conveyance of milk and butter by railway.

G. H. TURNER.

27th November, 1900.

(1) Are any special trucks set apart for the conveyance of milk or butter?—Special vehicles are used for the conveyance by passenger train of full loads of milk in churns. Butter is not conveyed in specially constructed wagons but generally with other articles by goods train.

(2) Are these commodities sent alone or in conjunction with other articles, and, if so, why?—If not a full truck load butter forwarded by the goods train service is loaded along with other goods. Butter in small quantities and occasional churns of milk are conveyed in luggage or parcels vans by passenger trains.

(3) Is milk or butter sent in refrigerating cars or in ice-wagons?—It is not our practice to use refrigerator vans for milk and butter.

(4) If not, have the wagons used for such produce double walls and roofs, and any special methods of ventilation?—The sides of vehicles provided specially for the conveyance of milk are boarded outside and inside, but the roof is not double. The ends and sides are louvered for ventilation.

(5) Do milk and butter go by passenger or goods trains?—Butter and condensed milk are principally forwarded by goods train. Fresh milk is chiefly sent by passenger train service.

(6) Are any special precautions taken to keep trucks so used in the shade during the heat of summer while awaiting their cargoes at provincial stations?—No.

Generally speaking the heavy milk traffic passes during the night.

(7) What are the maximum distances in one and another direction from which milk and butter are carried, and how many hours are occupied in the journey to London?—The maximum distances milk is conveyed by passenger train by our route from the North and West to London are:—Distance, Glasgow to London, 423 miles; time occupied, 12 hours. Berkeley Road to London, 197 miles; time occupied, 8 hours. We have no precise particulars of the transit of condensed milk and butter conveyed by goods trains.

(8) Is the milk and butter traffic on your railway extensive, and have any complaints been received as to damage of produce in transport?—The quantity of milk and butter carried by the Midland route is extensive. Complaints as to damage in transit are comparatively few, and it is generally found that, in the case of butter, the damage arises through the defective packages used by the senders.

Midland Railway,

General Manager's Office,  
Derby, November, 1900.

## SOUTH-EASTERN AND CHATHAM AND DOVER RAILWAYS.

I have the pleasure to send you herewith for the information of the Food Preservatives Committee replies to the inquiries propounded by them, both as regards our passenger and goods departments.

A. WILLIS,  
General Manager.

19th October, 1900.

## Conveyance of Milk and Butter by Railway.

## PASSENGER.

(1) No milk and butter are conveyed in the ordinary luggage vans.

(2) These commodities are sent in conjunction with luggage and ordinary parcels.

(3) No.

(4) No.

(5) Butter by both, but milk by passenger almost exclusively.

(6) No.

(7) With regard to milk about 50 miles.

(8) Milk traffic comparatively not extensive.

## GOODS.

(1) Butter is sent in ordinary trucks.

(2) With ordinary merchandise, unless there is enough to fill a truck, and in that case the butter is sent by itself.

(3) As to butter, no.

(4) No.

(5) Principally by goods.

(6) Yes, so far as is practicable, but consignees are eager to receive early.

(7) Butter by goods trains is sent a maximum distance of 86 miles from London.

(8) Traffic from London heavy.

## APPENDIX No. X.

AN HISTORICAL RECORD OF THE USE OF PRESERVATIVES AND COLOURING MATTERS IN FOOD, GLEANED FROM THE VOLUMES OF THE "LANCET," from 1851 to the present time. By Mr. S. A. Vasey, F.I.C., F.C.S., Consulting Chemist to the "Lancet."

Attention was drawn incidentally to the preservation and artificial colouring of food with the commencement of the labours of the Analytical Sanitary Commission of the "Lancet," which was instituted in the year 1851 by the late Mr. Thomas Wakley, M.P., the founder of the journal. The gross forms of fraud which this Commission brought to view are in the main not related to the specific subject which the present Committee on Preservatives are considering. Nevertheless, some important points are touched upon which bear distinctly upon the history of the employment of preservatives and colouring matters in food, which I venture to think will be of interest to the Committee.

The first report, dealing with the adulterations of Coffee, contains little that is germane to the subject, but in the "Lancet" of 20th September, 1851, the Adulterations of Milk are described. In this article mention is made of the use of turmeric added for the purpose of producing in milk a richness of colour, making the dilution with water and abstraction of cream less apparent. In the same article reference is made to the addition of carbonate of soda to prevent milk from turning sour. Milk thus treated may be kept, it is said, for eight or ten days. Again, milk of almonds is referred to as being sometimes present in milk, and as oil of almonds is decidedly antiseptic the object of its addition was probably for preserving purposes or as a corrective. This seems to be the first historic reference to the use of preservatives in milk.

The next reference to the use of a preservative is in connection with the addition of sulphuric acid to Vinegar. The "Lancet" Commission (the "Lancet," p. 52, Vol. I., 1852) regarded this addition as unnecessary since some makers dispensed with it altogether. As a result of the enquiry it was shown that of 33 samples analysed eight samples contained a quantity of sulphuric acid not exceeding the amount permitted to be added, while in the remaining cases the amount exceeded this, and in some instances was three or four times as great.

The next enquiry (1852) related to Pickles and their adulteration, and here again the presence of free sulphuric acid was shown and of copper in varying amounts in the samples purchased. In two instances the amounts were poisonous. The pickles which contained the largest quantity of copper were those which consisted entirely of green vegetables, as girkins and beans. "One of the worst features of this abominable practice," remark the "Lancet" Commission, "is that the employment of copper is wholly unnecessary as the colour of green vegetables may be very well preserved by other means as by the use of pure vinegar and the addition of a proper quantity of salt."

The next important article dealt with Preserved Provisions, and appeared in the "Lancet" of 20th March, 1852. In this article reference is made to the means of preserving various foods, but the only preservatives mentioned are salt, sugar, oil, charcoal, acetic acid, pyroligneous acid, and alcohol. A number of samples was examined, including carrots, turnips, peas, rhubarb, cabbage, Brussels sprouts, potatoes, apples, extract of beef, soups, fish, and beef pemmican. Out of the 34 samples of preserved provisions of all kinds submitted to examination the condition of preservation of 29 was most satisfactory, the state of five only out of the number being unsatisfactory, three of these being vegetables. It is concluded on the whole that the several processes adopted for the preservation of vegetable and animal substances, so far as regards home and domestic use, are productive of satisfactory results. From the few cases, however, which have turned out unfavourably it is evident that the greatest care is requisite in conducting the several steps of whatever process is adopted.

The next report was devoted to the examination of Cayenne Pepper purchased at the establishments of grocers and oilmen resident in the metropolis, and the results were startling. Cinnabar, vermilion, or sulphide of mercury was detected in one sample. Six of the

samples consisted of a mixture of ground rice, turmeric, and cayenne coloured with either red lead or a red ferruginous earth. Venetian red, red ochre, brick dust, occurred in seven samples, red lead in poisonous quantities in 13 samples, while of the 28 examined 22 contained mineral colouring matter. Practically the same substances and colouring agents were found in Curry Powder, the report, including the analysis of 26 samples, appearing in the "Lancet" of 17th July, 1852.

The next Commission dealt with Preserved Bottled Fruits and Vegetables. Twenty-seven samples out of 33 contained varying quantities of copper. This was true for gooseberries, rhubarb, and greengages, but not for red fruits like currants, raspberries, and cherries. Several specimens of green fruits and vegetables were free from copper. Olives contained a very large amount of copper. The colour of green fruit and vegetables is, the Commission remark, apparently heightened by a second device; the bottles in which they are enclosed are made of a highly-coloured glass; those in which French olives are preserved are so intense a green as to impart to the fruit a deep green colour even without the aid of copper.

The next enquiry of interest to the Committee related to Anchovies, in which red lead was occasionally found. In 23 out of 28 samples bole Armenian or Venetian red was found. Much the same class of colouring material was found in many samples of potted meats and fish, the report appearing in the "Lancet" of 13th November, 1852.

The next enquiry related to Sauces, in which apparently in some instances charred deal wood was used for imparting colour. Cochineal and bole Armenian were found in essence of lobsters, shrimps, and anchovies.

An interesting letter appeared in the "Lancet" of 15th January, 1853, from the late Dr. Bernays, Lecturer on Chemistry at that time in St. Thomas's Hospital. Referring to the work of the "Lancet" Analytical Sanitary Commission, Dr. Bernays records that when eating gooseberries with a steel fork he observed the prongs to be completely coated with a thin film of bright metallic copper.

Preserves and Jellies were next the subject of enquiry, the results being recorded in the "Lancet" of 22nd January, 1853. Some 35 samples were examined. Raspberry jam, gooseberry jam, greengage jam, the greengages of crystallised fruit, limes, and greengages, and candied citron peel, all owed their brilliant colour to a salt of copper.

The next subject forming the basis of a report was Lard, where the chief form of adulteration appeared to be caustic lime "to improve consistence and colour."

Later, in the "Lancet" of 4th June, 1853, it is shown that Butter is heavily preserved with an excess of salt, but no other preservative is mentioned.

A pause appears to have occurred at this date in the work of the Commission, the next article appearing in the "Lancet" of 3rd December, 1853, which related to the analysis of 43 samples of Snuff. In many instances red ochre, yellow ochre, and umber were found for colouring purposes. Chromate of lead, oxide of lead, and bichromate of potash were found in other samples.

In the following year, in the issue of the "Lancet" of 27th May, 1854, appeared a remarkable report on the "Colours used in Confectionery." Yellow sweets were found coloured with chromate of lead and gamboge; the red sweets were coloured with red lead, vermilion, or sulphide of mercury; the brown sweets were coloured with umber and sienna; the purple sweets with Prussian blue and cochineal; the blue sweets with indigo, Prussian blue, and ultramarine; the green sweets with Brunswick green, a mixture of chromate of lead and Prussian blue; and others were coloured with carbonate of copper and Scheele's green or arsenite of copper. In cake ornaments white lead was frequently found. In this report several instances are given of poisoning by the consumption of articles so coloured.

## Appendix.

With this terrible indictment the work of the Commission as it relates to the subject of enquiry before the Committee on Preservatives ceased until seven years later. In 1861 and 1865 the *Lancet* Analytical Commission resumed its enquiry, and this time devoted its attention again to Preserved Provisions, in which it was shown that copper was still employed to a very large extent in green preserved fruits and vegetables, although the samples obtained from big firms which are still well known were shown to be free from copper. Also it was shown that the gross forms of adulteration of Cayenne, as with lead and mercury, had to a large extent subsided. In the same year it was also shown that Mustard was less adulterated, and that turmeric as a colouring agent was the exception rather than the rule. There is a vast amount of further information in these reports bearing on the general adulteration of food up to that time. It would clearly appear that up to this date the present methods of preserving and colouring foods were unknown. That attempts were, however, very strenuously made to institute a satisfactory method for the preservation of food is abundantly clear from a perusal of the "*Lancet*" from 1854 to 1886. Editorial articles appeared again and again as to the merit of certain processes, and analyses were quoted clearly emanating from the "*Lancet*" Analytical Sanitary Commission, dealing with the product of these methods. It is interesting to refer to one article, which appeared in the "*Lancet*" of 19th January, 1867.

In this article the efforts that have been made towards preserving Animal Food Supplies are described. Omitting to mention the methods of tinning meats in vacuo we may refer for the purposes of the present enquiry to the section of this article which deals with antiseptics. It would appear that sulphurous acid and the sulphites were tried, with the result that though to some extent the meat was preserved from putrefaction, yet the flavour of the meat so treated put the method out of court. The use of nitric oxide was also suggested. In summing up the "*Lancet*" writes, "It may be safely asserted that no method is known to science by which the decomposition of raw meat can be prevented, especially in tropical climates, without the employment of some powerful antiseptic which, in order to accomplish the object, must impregnate every part of the meat and its juices. It may also be safely asserted that there are no known antiseptics capable of producing the required effect that would not either destroy the nutritive properties of the meat or communicate to it a decided flavour that would interfere with its use as a food. Salt is the only chemical agent that has been used with any good effect, but something better than salt meat is wanted." Here again there is no mention of the use of modern antiseptics like borax.

Apparently the first mention of a modern preservative in Milk was in the "*Lancet*" of 20th January, 1877.

The preservative was salicylic acid. Next, in the same journal of 11th January, 1879, borax is mentioned as being used in meat.

It is curious to note that the employment of modern antiseptics for the preservation of food was introduced much about the time when Lord Lister introduced his method of antiseptic treatment. Lord Lister's discovery was made in 1870, and in the following years the Listerian methods were adopted, with what remarkable results in the history of medicine every medical man knows.

In 1886, Vol. I., page 700, an editorial note appears in the "*Lancet*" on the "Increasing Use of Preservatives in Food." Benzoate of soda appears then to have been regarded as the best agent. Boric acid is described as undesirable and injurious, especially when present in milk for infant use.

In another article, which appeared on p. 1142, Vol. II., 1886, the results of the examination of Borated Fish are reported. Here it is stated that apparently boric acid is not truly a preservative, and blackening of the flesh was noticeable.

Then, in several articles which appeared in the second volume of the "*Lancet*" in 1887, the increasing use of Boric Acid in Milk was pointed out, and appeal was made for attention to the subject. One of these articles was the translation of Dr. Forster's Report in Dingler's "*Polytechnisches Journal*," 1884, page 170, on the use of boric acid as a so-called food preservative. This will be found to be a very interesting physiological enquiry, which would appear to have anticipated modern experiments. The result was distinctly unfavourable to the use of boric acid.

The publication of this article in the columns of the "*Lancet*" led to what must be regarded as the first public agitation on the subject. It received considerable comment at the hands of the public analysts, which culminated in the first case of prosecution instituted under the Sale of Food Acts. The case failed on the point of an added, and as it was urged, injurious preservative, but succeeded on the point of abstraction of fat.

In a leading article in the "*Lancet*" of 10th January, 1891, in commenting upon this case, the "*Lancet*" remarked that the "question is an important one and calls for immediate investigation, and the consensus of medical opinion must be gained."

This is exactly the present position, and a position which the Committee are appointed to elucidate. As to the evidence of the use of preservatives and colouring matters in food following the date of this remark (10th January, 1891) up to the present time, particulars have already been furnished to the Committee by medical men, public analysts, and myself.

The "*Lancet*" Laboratory,  
29th November, 1899.

## APPENDIX No. XI.

Handed in by Mr. T. Carrington Smith on Wednesday, January 17th, 1900.

TABLE A.—STATEMENT giving NAMES of PRESERVATIVES used in various descriptions of Dairy Produce, and the quantities or proportions in which they are used by persons who have complied with a request for information on the subject.

| No. | Farmer, Dairyman, or Dairy Factory. | Preservative.                                        | Used for.              | Quantity or Proportion in which used.                                                                                                                              | Remarks.                                                                                 |
|-----|-------------------------------------|------------------------------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| 1   | Dairy factory                       | Borax and boracic acid                               | Butter and cream       | $\frac{1}{2}$ to $\frac{3}{4}$ per cent. Smaller quantities would not answer. Mixture consists of Borax 50 per cent., boracic acid 40 per cent., salt 10 per cent. | Prohibition would kill English butter and cream trade.                                   |
| 2   | Dairyman                            | Formaldehyde                                         | Milk                   | 1 part in every 20,000 parts                                                                                                                                       | Prohibition would injure business.                                                       |
| 3   | Dairy factory                       | Glacialine                                           | Milk                   | 1 oz. to 18 imperial gallons                                                                                                                                       | Used occasionally.                                                                       |
|     |                                     | Glacialine                                           | Potted cream           | 1 oz. to 5 imperial gallons of cream.                                                                                                                              |                                                                                          |
|     |                                     | Boracic acid                                         | Milk and cream         | Does not preserve so well, therefore adds twice as much to be effective.                                                                                           |                                                                                          |
| 4   | Dairyman                            | Glacialine                                           | Milk                   | 2 oz. to 16 gallons.                                                                                                                                               |                                                                                          |
|     |                                     | Arcticannus                                          | Cream.                 |                                                                                                                                                                    |                                                                                          |
| 5   | Dairyman                            | Formalin                                             | Milk                   | $\frac{1}{2}$ pint of 3 gallon solution in 16 gallon churn.                                                                                                        |                                                                                          |
|     |                                     | Preservitas                                          | Cream                  | With 7 lb. of sugar added to 14 lb. of powdered preservitas, 1 oz. in 20 quarts.                                                                                   |                                                                                          |
| 6   | Farmer                              | Borax                                                | Milk                   | 1 oz. to 50 gallons                                                                                                                                                | Only used about one month in the year.                                                   |
| 7   | Dairyman                            | Arcticannus                                          | Cream                  | April to September $\frac{1}{4}$ oz. per gallon, October to March $\frac{1}{2}$ oz. per gallon.                                                                    | Prohibition would cause serious loss and waste of valuable dairy products.               |
| 8   | Dairyman                            | Preservitas                                          | Butter                 | 1 per cent.                                                                                                                                                        | In bad weather only.                                                                     |
| 9   | Dairyman                            | Douglas's dry antiseptic                             | Milk, cream and butter | 2 oz. to 30 gallons of milk.                                                                                                                                       | Total prohibition would be a distinct advantage in West of England.                      |
| 10  | Dairyman                            | Formalin                                             | Milk                   | 1 in 20,000                                                                                                                                                        |                                                                                          |
|     |                                     | Glacialine                                           | Cream                  | As directed.                                                                                                                                                       |                                                                                          |

## Appendix.

TABLE A.—STATEMENT giving NAMES of PRESERVATIVES used in various descriptions of Dairy Produce, &c.—*continued*.

| No. | Farmer, Dairyman, or Dairy Factory. | Preservative.               | Used for                       | Quantity or Proportion in which used.                                           | Remarks.                                                                   |
|-----|-------------------------------------|-----------------------------|--------------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| 18  | Farmer -                            | Crystalline                 | Milk -                         | 1 tablespoonful to 17 gallons                                                   | Prohibition not injurious if applied all round.                            |
| 19  | Dairy factory                       | Borax                       | Butter -                       | 1 lb. dissolved in 8 gallons of water; 1 pint of solution to 8 gallons of milk. | Impossible to carry on milk trade in hot weather without preservative.     |
| 20  | Dairyman -                          | Middleton's antiseptic      | Milk -                         | A little dry powder.                                                            | Prohibition would greatly injure business.                                 |
| 21  | Dairy factory                       | Middleton's antiseptic      | Cream -                        | 1 oz. per gallon                                                                | Sends milk twice daily, and does not now receive preservative from dealer. |
| 22  | Farmer -                            | Special cream preservative  | Cream -                        | 2 oz. to 17 gallons in 1896                                                     |                                                                            |
| 23  | Dairyman -                          | Boracic acid                | Milk -                         | 1 in 20,000.                                                                    |                                                                            |
| 24  | Dairyman -                          | Formalin                    | Milk -                         | Variable                                                                        | Sent by purchasers.                                                        |
| 25  | Dairy factory                       | Glacialine and Arcticanus   | Cream -                        | 1 oz. dry to 16 gallons.                                                        |                                                                            |
| 26  | Dairyman -                          | Boracic acid and borax      | Milk -                         | $\frac{1}{2}$ oz. to the gallon.                                                |                                                                            |
| 27  | Dairyman -                          | Conservine                  | Cream -                        | $\frac{1}{2}$ oz. to the gallon.                                                |                                                                            |
| 28  | Dairy factory                       | Arcticanus                  | Cream -                        | $\frac{1}{2}$ oz. to 1 oz. to each imperial gallon of cream.                    | Prohibition would absolutely ruin cream trade. Only used occasionally.     |
| 29  | Dairyman -                          | Golden Cross brand          | Butter -                       | $\frac{1}{2}$ oz. to 1 oz., according to season                                 |                                                                            |
| 30  | Farmer -                            | Preservitas                 | Milk -                         | $\frac{1}{2}$ per cent.                                                         |                                                                            |
| 31  | Farmer -                            | Arcticanus                  | Milk -                         | 3 quarts of liquid preservative to 60 gallons of milk.                          |                                                                            |
| 32  | Dairy factory                       | Sal preservare              | Cream -                        | 1 teaspoonful to 4 gallons of milk.                                             |                                                                            |

| Annatto- - - - -                    | Forty-two.       | Howarth Colouring Fluid - - - - -      | One.             |
| Danish Butter Colouring - - - - -   | Five.            | Tomlinson's Butter Colouring - - - - - | One.             |
| Silver Churn - - - - -              | Five.            | Grated carrots - - - - -               | One.             |
| Primrose Butter Colouring - - - - - | Two.             | Colouring XXX. - - - - -               | One.             |
| Oleo Butter Colourine - - - - -     | Two.             | Jersey Butter Colouring - - - - -      | One.             |
| Cowslip Colouring - - - - -         | Two.             | Butter Cup Colouring - - - - -         | One.             |
| Carrotine - - - - -                 | One.             |                                        |                  |

COPY of a Resolution passed at the Annual General Meeting of the Central Chamber of Agriculture, held on December 6th last, on the motion of Mr. S. KIDNER, representing the Taunton Farmers' Club, seconded by Mr. C. MIDDLETON, representing the Cleveland Chamber:—

"That this Meeting is opposed to the employment of preservatives and colouring matters in articles of dairy produce, whether British or imported; and that it be an instruction to the witnesses appointed by this Chamber to give evidence before the Departmental Committee to urge that, as preservatives and colouring matters are believed to be deleterious to the health of invalids and children, their use should be prohibited."

## APPENDIX No. XII.

Appendix.

Handed in by Mr. W. W. FISHER, January 17th, 1900.

REPORT expressing the general experiences of the members of the Society of Public Analysts.

Since my former communication to your Secretary, I have been able to gather further information, which I have the honour to submit to the Committee.

A schedule of articles of food and drink, prepared by the Society of Public Analysts, was sent to members with the request that they would furnish any information they could in regard to the use of preservatives and colouring matters, and a number of analysts have kindly contributed the results of their experience. Through the kindly co-operation of the authorities for whom I act, many articles have been purchased for analysis, which have been specially examined in view of this enquiry, but although this assists in filling up some gaps, it will be seen that much remains to be done in respect of a large number of articles.

It will probably be convenient to classify the articles in five groups:—

- I.—Fresh meat, etc., preserved meat, fish.
- II.—Dairy products.
- III.—Vegetables, fruit, confectionery.
- IV.—Beverages, alcoholic and non-alcoholic; sauces, condiments.
- V.—Drugs and vegetable extracts.

#### I.—FRESH MEATS, ETC.

*Fresh Meats.*—Beef, mutton, pork, veal, venison, poultry, game.

*Potted and Prepared Meats.*—Dried Meats, meat powders and biscuits, sausages, bacon and ham, salt beef, salt pork, smoked meats, meat extracts, meat juices, soups, tinned and potted meats, jellies.

Many of these articles are never purchased for analysis, and no information is available either as regards the use of preservatives or artificial colouring.

*Sausages.*—These articles are frequently coloured. In the North of England Mr. Allen of Sheffield finds Congo red is used very generally; Mr. Keating Stock (Durham) has met with a mixture, parts of borax and boric acid coloured with Congo red, which is used as a preservative for meats. Mr. J. W. Gatehouse, of Bath, states that species of eosine dye, known as "theodine," is largely used, and he has advised its discontinuance, as it is likely to be injurious to health. Mr. Bodmer (Southwark) has met with red colouring matter, probably an aniline dye. In the Oxford district a small proportion of red oxide of iron is used sometimes as a colouring in German sausage, but the red appearance is mainly due to the presence of saltpetre in the brine used for salting; the red colour is occasionally enhanced by artificial dye upon the outside skin of the sausage.

A boracic preservative is not infrequently used. Dr. A. Hill records it in sausages and in German sausage, and in polony he has found '65 per cent. boric acid; in chicken, ham and tongue '6 per cent.

Of five makes of German sausage lately examined I found three containing boracic acid in the proportion of '45 per cent.  $H_3BO_3$ , '34 per cent. and '37 per cent. severally.

Dr. Dyer has detected in pork sausages quantities up to '7 per cent.

*Bacon and Ham.*—Mr. Gatehouse says borax is largely used for hams. "Curers assert public taste requires this treatment, and the old salt and saltpetre pickle will not sell, and besides is much too long in operation. The latter, it may be presumed, is the true reason. Impure calcium sulphite mixed with much sulphate was offered to a large bacon curer for rubbing into sides of bacon, but it is not known if this was actually used."

Dr. Bernard Dyer states that out of 34 samples of bacon and ham submitted to him because suspected, 14 contained boracic acid; one ham contained from '5 to '75 per cent. in different parts.

3017.

Dr. A. Hill has found bacon to contain '4 per cent. boric acid, ham '15 per cent., and salt beef '45 per cent. of boric acid.

Dr. Rideal gives '04 per cent. of borax as the amount in American ham, and several other gentlemen mention the presence of boracic preservatives in bacon and ham. I am informed that "A Manual of the Pork Trade" was published by L. Upcott Gill (170, Strand, London) by Mr. M. L. Douglas, but is now out of print, and I have not yet seen a copy. It contains recipes for all sorts of sausages, pork pies, etc., as well as information about bacon curing, and would doubtless afford much information to the Committee. As an ingredient of almost everything, "dry antiseptic," which is a mixture of borax and boracic acid, is recommended, usually in the proportion of about  $\frac{1}{2}$  per cent.

In respect of meat extracts I have little information, but Mr. Allen has met with boric acid in one make. Mr. Clayton also mentions its presence, while Mr. R. Bodmer states that 9 per cent. of boracic acid was present in a liquor used for pickling livers. I have recently examined samples of tinned salt beef, tinned rabbit, potted meat, and potted beef, but no preservative beyond salt and saltpetre was discovered. Dr. A. Hill has met with boracic preservatives in pork pie, salt beef, and pickled tongue, and my colleague, Dr. T. Stevenson, informed me that borates are used for venison, poultry, bacon, ham, as well as for salt pork, salt fish, and fresh fish.

Meat juices sometimes contain glycerine.

Table jellies lately examined were free from preservatives, but some contained artificial dyes, a diazo yellow and a red.

*Fish.*—Mr. Allen has observed much boracic acid in herring brine, and Dr. Hill has found this preservative in salt fish.

In tinned lobster recently examined I found no preservative beyond a little salt; in bloaters I have found the ash, mainly consisting of salt, varied from 15.9 per cent. to 9.8 per cent., but in one sample was only 6.5 per cent.; this was a tinned article. No boracic acid was present in any case. Four specimens out of six examined contained red oxide of iron (probably ochre or Armenian bole) as a colouring matter; the proportion of ferric oxide determined ranged between '34 per cent. to '05 per cent.

An anchovy paste contained 17.4 per cent. ash, nearly all salt, a little oxide of iron, and traces of a sulphite preservative.

Two samples of smoked fish examined by Dr. Dyer were free from boracic acid.

One of our members, Mr. Henry Leffmann, of Philadelphia, sends the following information as to the composition of meat preservatives, from the report of a local board of health:—

#### (1) Solution of Calcium Sulphite.

#### (2) Conserve for Sausages.

|                   |   |   |               |
|-------------------|---|---|---------------|
| Potassium Nitrate | - | - | 33.5 grammes. |
| Boric Acid        | - | - | 27.5 "        |
| Glycerol          | - | - | 50.0 "        |

#### (3) Preserving Salt.

|                    |   |   |                |
|--------------------|---|---|----------------|
| Borax              | - | - | 48.5 per cent. |
| Sodium Chloride    | - | - | 3.5 "          |
| Sodium Bicarbonate | - | - | 9.1 "          |
| Water              | - | - | 39.0 "         |

#### (4) Ham Preserver:

|                   |   |   |               |
|-------------------|---|---|---------------|
| Potassium Alum.   | - | - | 70.0 grammes. |
| Potassium Nitrate | - | - | 21.0 "        |

Some of these meat preservatives contain a coal-tar dye to assist in reddening the meat.

## Appendix.

Mr. J. Hendrick (Aberdeen) sends the analysis of a liquid intended to be sold as a preservative for fish; it contained 1·37 anhydrous boron oxide, a little glycerine, and ·5 per cent. common salt. The total solids were 3·29 per 100 c.c.

Mr. H. Droop Richmond, analyst to the Aylesbury Dairy Company, Limited, who has examined a number of commercial preservatives, has most kindly furnished the following particulars of their composition:—

ANALYSIS OF COMMERCIAL PRESERVATIVES.

|    | Mixtures of Borax and Boric Acid. |                                               |                                     | Calculated as                  |                                                                   |

| 10 | 39·5                              | 26·8                                          | 58·1                                | 70·0                           | 50·7                                                              |

Average, 56·8 per cent. of B<sub>2</sub>O<sub>3</sub>.

He has also met with a preservative containing a mixture of borax and boric acid, with about 5 per cent. of salicylic acid.

Another preservative analysed contained boric acid equal to 7·46 B<sub>2</sub>O<sub>3</sub> or 13·25 per cent. H<sub>3</sub>BO<sub>3</sub>, and combined salicylic acid 12·87. The ash contained a little calcium, much magnesium and sodium. Glycerol was found in large quantity, and an unidentified bitter principle, probably to mask the taste of glycerol, was present. The alkalinity of the ash corresponded with the quantity of salicylic acid.

This preparation consisted essentially of a solution of boric acid and sodium or magnesium salicylate in glycerol.

## II.—DAIRY PRODUCTS.

*Milk, new, skimmed or separated, condensed; butter milk; cream, new, and in pots; Devonshire cream, butter, margarine; cream cheese, fancy cheeses, English cheese, imported cheese, margarine or filled cheese; junket.*

The testimony as to the use of preservatives in milk and some other dairy products is universal, but in different parts of the country the extent to which the practice is adopted is variable, and I will briefly mention the experiences of my colleagues, which they have furnished.

Mr. A. H. Allen, of Sheffield, Analyst to the West Riding of Yorkshire, etc., states that formalin and boric acid are found in milk, the latter up to 1 per cent.; the boracic acid is also used with cream in pots, butter, and margarine, up to the same limit.

Dr. Bernard Dyer, of London, Analyst for the counties of Leicester, Rutland, and Wilts, etc., informs me that out of 270 milks recently examined for boracic acid, only one sample contained it; and adds that these are country retailed milks. Further, out of 234 samples of butter, 30 contained boracic acid ranging from 0·03 per cent. to 1·35 per cent., but it is rare to find more than 0·75 per cent.

Of 30 samples—

|    |      |      |                     |
|----|------|------|---------------------|
| 8  | gave | 0·25 | per cent. or less.  |
| 12 | „    | 0·26 | „ to 0·50 per cent. |
| 7  | „    | 0·51 | „ to 0·75 „         |
| 1  | „    | 1·06 | „                   |
| 1  | „    | 1·35 | „                   |

In Dec. 1899 seven butters were purchased under the Act in Oxford, and boracic preservative was present in four up to 1·2 per cent. of H<sub>3</sub>BO<sub>3</sub>.

The use of the preservatives is also noted by the Analyst for Shropshire, Montgomeryshire, Merionethshire (Mr. T. P. Blunt), Mr. Harvey, of Canterbury, etc., who meets with boracic compounds occasionally, but thinks they are less used than three years since. Mr. J. W. Gatehouse, of Bath, says boric acid compounds and borax are largely used; Formalin rarely in that neighbourhood. "The hospital authorities in Bath believe that boric compounds are seriously injurious to their patients."

Mr. Hendrick, of Aberdeen, records that borax and boric acid are used in milk and butter, but only to a limited extent, in the district. He found in a recent case that glacialine contained 58 per cent. of anhydrous B<sub>2</sub>O<sub>3</sub>; also alkali corresponding to 28 per cent. of borax. Anatto is used for colouring.

Dr. Alfred Hill, of Birmingham, has met with boric acid in milk, etc., in the following quantities:—

|                |   |   |                      |
|----------------|---|---|----------------------|
| Milk           | - | - | up to 0·18 per cent. |
| Separated Milk | - | „ | ·01 „                |
| Cream in pots  | - | „ | ·3 „                 |
| Clotted Cream  | - | „ | ·35 „                |
| Butter         | - | - | „ 1·6 „              |
| Margarine      | - | - | „ 1·1 „              |

Formic aldehyde in milk and salicylic acid in cream are also reported by him.

Mr. W. F. Lowe, of Chester, Public Analyst for Flint, Carnarvon, Denbigh, etc., finds the following proportions of boric acid:—0·07 per cent. in new milk, ·27 per cent. in cream in pots, and in butter, ·10 per cent. to ·71 per cent.

Dr. S. Rideal, Analyst for the Lewisham district, has found in cream purchased under the Act, ·35 per cent. boric acid; in butter, ·136 per cent.; in margarine, ·48 per cent. (as crystallized borax); and in private samples of butter ·286 per cent. of boric acid. Imported butter: sometimes formaldehyde in centre of tub of butter, and boric acid on surface, used in wrapping paper.

The cream in pots sold in Newcastle-upon-Tyne contains boracic acid from ·05 to ·31 per cent.

The analyst for Durham County, Mr. Keating Stock, also records the use of borates, and Dr. Stevenson, Analyst for the counties of Surrey and Bedford, observes that borates and formaldehyde are used for new milk and tropæolins to colour; also in separated milk; while cream in pots, butter, and margarine are similarly preserved with borates. Dr. Stevenson states also that borates are used on the outside of imported cheese to keep off insects.

On the authority of Mr. H. Leffmann, of Philadelphia, I learn that paraffin and glucose are sometimes used in butter substitutes.

I should like to call the attention of the Committee to a table in the "Analyst" for June, 1899, by Mr. E. G. Clayton, from which it would appear that the use of boracic preservatives has declined in recent years in some parts of London.

I may add to the facts already communicated to your Committee that during the past quarter I have examined 29 milks from Buckinghamshire and Oxfordshire, none of which contained preservatives, but two samples of new cream sold in Oxford, of which complaint was made, were found to contain boracic preservative, in one instance upwards of 1 per cent. of the acid. I subsequently learned that this cream came from a dairy company in Dorsetshire.

Mr. H. Droop Richmond, analyst to the Aylesbury Dairy Company, has kindly sent us a statement on the subject of dairy products which is extremely valuable. He says, "In submitting the following list it must be understood that most of the information is derived from analyses and enquiries made without any special object in view;" and that he has little or no experience in the use of preservatives on a commercial scale, as the Aylesbury Dairy Company have always been antagonistic to their use; and that he has only a small amount of information, chiefly hearsay, of what is done by the trade generally.

The following substances are extensively treated with preservatives:—

Milk, new.

Milk, condensed (unsweetened), occasionally.

Milk, skimmed or separated, chiefly because the milk used for their preparation is preserved.

Cream, new. Cream in pots universally.

Devonshire cream (when sold in pots).

Butter. Margarine sometimes.

The following are not usually preserved:—Butter milk, cream cheese, fancy cheese, English cheese, margarine cheese, and imported. Preservative would probably never be resorted to, as it would prevent the ripening of the cheese. Junket may occasionally contain preservatives if prepared with milk containing them.

Substances used: Boric acid, borax, or usually mixtures of the two are used in milk, cream and generally in butter. A solution of formaldehyde ("formalin") containing 1 per cent. is extensively used for preserving milk and cream, and less frequently butter. Benzoates, salicylic acid, and salicylates, sodium fluoride, sodium fluosilicate, fluoboric acid, and fluoroborates and potassium nitrate are among substances which have from time to time been used, but are probably but little employed.

The quantities used are as follows:—

Boric preservative in milk, .05 to .1 per cent.; in cream, .05 to .25 per cent.; in butter, .1 per cent., when the butter is washed with the solution, or .5 to 1 per cent.

Formalin is used in the proportion of one part of formaldehyde per 200,000 in milk, and from this to double the amount in cream.

The boric preservative added to cream is usually the "special cream compound," which, in addition to boric acid and borax, may contain sugar to sweeten the cream and thickening substances.

Mr. Richmond makes the following comments also: "The object of preserving milk is to keep it from noticeable decomposition due to micro-organisms for a longer time than is possible if no precautions are taken. It has been found by the experience of the Aylesbury Dairy Company that by cooling as soon as possible after milking, the milk can in the hottest weather experienced in England be brought up by rail from distances from 30 to 200 miles of London, and be delivered to customers in a condition permitting its use within a reasonable time. By refrigeration to low temperatures, such as is the rule in Denmark, and by pasteurization, milk could easily be transported even longer distances without preservatives.

"To attain the object of keeping milk for a time longer than natural, the preservative would be advantageously added at the farm; further doses may also be added both by the wholesale dealer and by the retailer.

"The object of preserving cream is chiefly to ensure that there shall be no loss of this comparatively valuable product through decomposition; this is especially the case when it is sold in pots. The quantity used is greater than is added to milk, because it is required to keep for longer periods, frequently when in pots for over a week. The Aylesbury Dairy Company have found no difficulty in preparing and delivering cream in a fresh condition without the use of preservatives.

"The object of preserving butter is to prevent it becoming rancid and stale. (Rancidity is here taken to mean partial hydrolysis and liberation of lower fatty acids and staleness, partial oxidation and destruction of the flavour.) There is little evidence that the use of preservatives, even in the large amounts generally employed, have much effect, though decomposition is certainly delayed for a short period. Salt is nearly as efficacious in keeping butter from rancidity as boric preservatives, though its antiseptic power is much weaker. To further illustrate this, French butter is almost universally treated with boric preservative (see Table B), while Danish butter is universally free from this, but is salted. Trade experience has shown that no more complaints are received of Danish butter than of French butter—if anything, rather the opposite.

"There appears to be little necessity to add any preservative, unless salt can be thus classed, to well-made butter, if sold freshly made.

"B. Colouring Matters.—The whole of the substances enumerated as dairy products except condensed milk, which is very rarely coloured, and skimmed or separated milk, cream and junket, which would chiefly be coloured by being prepared from coloured milk, receive an addition of colouring matters.

"The colouring matters used are Annatto and organic dye stuffs chiefly of the tropæolin class. The quantity

used varies much according to the natural colour of the milk, etc., but may be taken roughly as 1 part per 300,000 in milk and 1 part in 100,000 in butter and cheese. The quantities are calculated for the colouring matter itself, but the quantities of the commercial colouring substances may be taken roughly at 10 times that of the pure substances.

"The original object of colouring was to preserve continuity of colour during those months of the year in which milk and its products were nearly white, but owing to a mistaken idea among the public generally that colour indicates richness, dairy products are often artificially coloured more highly than they would ever be naturally for the purpose of making them look rich.

"In his opinion, it would be an advantage if colouring matter were altogether prohibited; the whole trade would then be on the same footing, and no fictitiously enriched milk would then be foisted on the public."

TABLE B. (Mr. D. Richmond.)

Quantity of Boric Acid in French Butters.

### III.—VEGETABLES AND FRUITS.

*Fresh vegetables, pickled vegetables, vegetables in bottles and tins, fresh fruits, desiccated fruits, crystallised fruits, tinned and bottled fruits, jams, syrups, jellies, and confectionery.*

The preservatives used for vegetables are, as far as my observation goes, usually salt and sometimes salt-petre for pickles, with vinegar; but if the vinegar contains a sulphite preservative traces of sulphite may also be present. Turmeric is used to colour piccalilli. Vegetables in bottles and tins do not appear to be treated with preservative, but beans and peas are coloured with sulphate of copper. Dr. B. Dyer has found quantities ranging from 0.8 grains to nearly 7 grains per pound of crystallised sulphate of copper. Mr. R. Bodmer has noted that tinned beans and peas contained sulphate of copper up to 3½ grains per pound; Mr. J. Pattinson sends figures giving the copper as varying from .21 grains to 5.25 grains per pound; while Mr. Lowe finds from .005 to .01 per cent. of metallic copper is used, equal to .35 grains to .7 grains per pound.

"Among articles I recently examined I found that dried raisins were not treated with preservative, but two samples of desiccated apricots contained traces of sulphites. In tinned tomatoes, pears, apricots, and pineapple preserved in syrup no preservative substances were detected.

Jams frequently contain salicylic acid and artificial colouring matters. Dr. Dyer gives the proportion of salicylic acid as ½ grain to 1 grain per pound, and thinks it is probably used to preserve the fruit pulp. Mr. W. F. Lowe says that salicylic acid seems very generally used (in amounts between 0.01 to 0.06 per cent.), as it was found in more than 50 per cent. of the samples examined. The artificial colouring matters reported are "a colour resembling benzo-purpurine" by Mr. Stock, and rhodamine as being used to colour sweets and confectionery. Lead chromate has been used in confectionery; apparently it is no longer employed; but organic dyes, such as eosins, tropeolins, and others are used for sugar sweetmeats. Mr. Gatehouse mentions sugar dyed with yellow and brown aniline dyes, and once knew of a sugar dyed with a colour analogous to Bismarck brown, which produced violent sickness in a family.

Appendix.

A pendix.

Mr. H. Leffmann, Pa., informs us that for confectionery the following are largely used: Fluorescein, eosins, rhodamin, auramin, naphthol yellow S., Helvetia green, acridin red, Bismarck brown, and safranin. Among natural colours principally anatto, turmeric and chlorophyll.

For oils and fats, especially butter and butter substitutes some simple azo-colours of the type of Soudan I. are much used. Caramel is used for vinegar. Mineral colours made from zinc and copper are found extensively in canned vegetables, such as peas. For preservatives salicylic acid is largely used, but not so widely as formerly. It has been absolutely prohibited in the State of Pennsylvania, and this prohibition has been extended to all preservatives except sodium benzoate. This action has been taken, he says, partly at his suggestion, experiments having indicated that sodium benzoate is less objectionable than other preservatives. It is used in mincemeat, catsups, jams, and jellies.

#### IV. BEVERAGES AND SAUCES.

*Draught ale and stout, bottled beer, lager beer, cider and perry, wines, British wines, medicated wines, non-alcoholic wines or beer, spirit liqueurs.*

*Aerated waters, lemonade, ginger beer, sweet aerated drinks, lime juice, etc.*

*Temperance drinks.*

*Sauces, vinegar, condiments.*

The preservatives generally used for ales and beers are sulphurous acid or sulphites; the proportion of sulphurous acid is given by Mr. A. C. Chapman as 0.01 per cent., and Dr. Rideal found .009 per cent. in bottled beer. Boric acid is occasionally met with, and salicylic acid .03 g. per litre. The trade preparations intended for the preservation of articles of food and drink, which Mr. Chapman has met with were—Sulphurous acid and sulphites of (1) sodium, (2) potassium, (3) magnesium, (4) calcium, aluminium sulphate and sodium nitrate, chloral hydrate.

Salicylic acid and its sodium salt in several preparations, also benzoic acid in others. Dr. Stevenson has found salicylic acid in lager beer and non-alcoholic beer. Mr. Leffmann mentions fluorides. In respect of wines, salicylic acid is sometimes found in light sherries, orange quinine wine, ipecacuanha wine, also in unfermented wines. The proportion, according to Mr. Chapman, being .015 g. per litre. Dr. B. Dyer found 0.3 grains per ounce in orange quinine wine deficient in spirit.

Mr. J. W. Gatehouse gives the proportions as 1 to 2 parts in 500 in non-alcoholic wines or beer. Recently I found salicylic acid in a raspberry syrup, the proportion being about .05 per cent., and Dr. Rideal has found .03 per cent. in peach bitters.

Spirits are not treated with preservatives, but caramel and other unknown colourings are reported as used for whisky.

Lemonade is not reported as containing preservatives, but sulphites, salicylic acid and colouring dyes are found in some aerated and sweet drinks. In some cases a red and in others a yellow is added; I once identified in

"champagne perry," a sweet aerated drink, a scarlet azo-naphthol dye, the use of which, on my advice, was discontinued. Saccharin is mentioned as sometimes used in the place of sugar as sweetening for lemonade, sweet drinks, and temperance drinks, but this is hardly a preservative in the ordinary sense. Benzoic acid, on Dr. Rideal's authority, has been used in lemonade; formaldehyde in ginger beer, and salicylic acid in kola.

Vinegar may be preserved by sulphuric acid, or by sulphites; formalin may occasionally be used; and caramel is employed to colour by some makers. Recently five vinegars examined by myself officially were found to contain sulphites in small quantity—four were malt vinegars, and one of French manufacture. The proportion of sulphur dioxide in these samples was from .004 per cent. to .006 per cent. Dr. Hill reports .02 per cent. boric acid in vinegar.

By the courtesy of a firm making vinegar, and other preparations, I have been placed in possession of the following information on the subject of preservatives and colouring matters used in articles manufactured by them.

*Vinegar.*—Colouring matter, caramel; formalin is occasionally used in the proportion of 0.03 per cent. when there are complaints of cask vinegar not keeping; but owing to its producing a certain degree of flatness it is not now used in the bulk of the vinegar.

*British Wines.*—As these have to be sweetened to meet the public taste, the small amount of alcohol then contain is an insufficiently preservative; calcium bisulphite is usually added in the proportion of from 0.5 to 1 per cent. and the wine kept until all odour of sulphur dioxide has disappeared.

*Lime Juice and Lemon Cordial.*—These are extraordinarily fermentable substances. The process in use consist in sterilizing, replacing part of the sugar by non-fermentable dextrin and saccharin and adding salicylic acid in the proportion of 6 to 7 ounces to 56 gallons of liquid [1 in 1,280 or .08 per cent.]. But even this treatment is only partially effectual, and every season there are numerous complaints of fermentation. It may be mentioned that considerably more than this amount of salicylic acid has been found in the same preparations made by other firms.

*Non-Alcoholic Wines.*—Ginger, orange, black currant, etc. From 6 to 7 ounces of salicylic acid per hogshead is the smallest amount which will check fermentation over a long period. As soon as that amount is reduced complaints become numerous. In such cases as these sterilization cannot be used, since the wines are sent out in casks, and are expected to keep indefinitely.

*Lemonade and Aerated Drinks.*—Part of the sugar is replaced by saccharin. If thorough cleanliness be observed in the factory, no preservative is necessary, except occasionally in abnormally hot weather.

*Brewed Ginger Beer.*—This will keep perfectly for 2 to 3 months without preservative if properly made.

*Sauces and Condiments.*—Mustard is coloured with turmeric, and cayenne pepper is sometimes coloured. In samples of sauces examined, including many well-known kinds, no preservatives were found.

## APPENDIX No. XIII.

Appendix.

Handed in by Dr. A. Hill, November 24th, 1899.

## CITY OF BIRMINGHAM.

## APPENDIX No. XV.

Handed in by Dr. H. Handford, November 23rd, 1899.

## A.

REPORT of ANALYSIS of MILK received 14 November from Dr. Buckley, General Hospital, Nottingham.

17 November, 1898.

I am of opinion that this Sample contains Boric Acid to the extent of 28·96 grains per gallon. Other preservatives are absent.

(Signed) SAMUEL R. TROTMAN, M.A.  
City Analyst.

## B.

RECOMMENDATIONS of the MEDICAL COMMITTEE, General Hospital, Nottingham, with reference to the supply of Milk to the Hospital.

The milk should be supplied under a strict guarantee :

- 1st. That it shall be derived from Cows which are healthy [and which have been proved to be free from Tubercle by the Tuberculine Test].
- 2nd. That it shall contain a minimum of 3 per cent. of fat.
- 3rd. That it shall not contain, when delivered to the Hospital, Boric Acid, Salicylic Acid, Formalin, or any preservative or added or foreign substance whatever.
- 4th. That it shall be delivered fresh and in good condition to the satisfaction of the Matron.
- 5th. That the Cowsheds and Dairy whence the milk is derived shall have been inspected and approved by the Medical Officer of Health of the district where they are situated, under the Dairies, Cowsheds, and Milkshops Orders, 1885-6.

[The Medical Committee further recommend that a complete analysis be made of the milk by the City Analyst at least once a month.]

The whole of the above Recommendations, with the exception of the two paragraphs in brackets, were included in a Form of Tender which the Contractor has agreed to and signed.

## C.

7 October, 1899.

ANALYSIS of MILK received from the NOTTINGHAM GENERAL HOSPITAL, 6 October, 1899.

This sample is of good quality.

It contains per 100 parts—

|                |   |   |   |       |
|----------------|---|---|---|-------|
| Fat            | - | - | - | 3·40  |
| Solids not Fat | - | - | - | 9·08  |
| Water          | - | - | - | 87·52 |

Preservatives are absent.

(Signed) SAMUEL R. TROTMAN, M.A.  
City Analyst.

## D.

The Rural District Council of Basford.

115, Waterloo Crescent,  
Nottingham, 25 May, 1899.

I visited Mr. —'s Cowsheds at — on 5th January, 1899, and then made suggestions as to improving the ventilation. I visited them again to-day, and found my suggestions were carried out, and I now certify that the Cowsheds are in a good sanitary condition as regards ventilation, drainage and cleanliness; that the water-supply, on the constant system, is of good quality; and that the cleansing of the utensils is carefully carried out.

(Signed) G. B. WRAY,  
Medical Officer of Health.

## APPENDIX No. XVI.

## PERSONAL VIEWS ON THE USE OF PRESERVATIVES AND COLOURING MATTERS IN FOODS.

Handed in by Mr. W. F. Lowe, Public Analyst for the Counties of Flint, Carnarvon, Anglesey, and Denbigh, and for the City of Chester.

I consider that this use of preservatives in all but a very few cases should be entirely prohibited, for the necessity for them is entirely obviated by the use of cold storage, for by it practically all food, even fruit, can be preserved without deterioration by properly regulating the temperature of the refrigerator.

In most cases preservatives can hardly fail to be more or less injurious to health, and especially to the health of weak persons and young children. As an instance of this I had, during the hot weather of last summer, a sample of milk brought me for examination for preservatives, as it was believed to have made a baby two months old very seriously ill with troublesome vomiting, or, as the parents said, to have poisoned the child. This milk contained an exceedingly small amount of formalin, and probably would not have been at all injurious to strong persons; in fact, I believe no one else in the house suffered from it.

The doctor who attended the case attributed the illness to the formalin acting as an irritant.

The habitual use of the powerful drugs used as preservatives is also very liable to injure the digestive organs of strong people by arresting or retarding the action of the natural ferments of the human body.

3017.

The proportion of various drugs capable of arresting the action of enzymes is given in the following table from Lauder Brunton's "Pharmacology and Therapeutics," page 78:—

|                 | Diastase. | Ptyalin. | Pepsin. | Pancreatin. |
|-----------------|-----------|----------|---------|-------------|
| Copper Sulphate | 1 : 6500  | 1 : 7500 | 1 : 110 | 1 : 6600    |
| Salicylic Acid  | 1 : 5100  | 1 : 1250 | 1 : 250 | 1 : 9000    |
| Benzoic Acid    | 1 : 1025  | 1 : 2600 | 1 : 200 | 1 : 2600    |
| Sulphurous Acid | 1 : 8600  | 1 : 8600 | —       | —           |
| *Borax          | 1 : 100   | 1 : 100  | —       | —           |

\* Contains 37 per cent. of boric acid.

The table gives the amount of the drug capable of arresting the action of the ferment, but no doubt injury may be done to the human body by lessening the action of natural ferments without actually arresting their action.

Besides its action on enzymes each of the drugs used as a preservative has its own special therapeutic effect.

## Appendix.

Boric acid, for instance, in large doses is said to produce sickness and diarrhoea, and in small doses to produce certain skin diseases. That it is a much more powerful drug than it was originally thought to be is proved by the dose in the new edition of the British Pharmacopoeia, 1898, having been reduced to one-half (from 30 grains to 15 grains).

Salicylic acid is said to produce chronic dyspepsia if taken regularly, even in very small quantities.

Another very strong objection to the use of preservatives is that they may be added to food that is already beginning to undergo decomposition, and which is therefore unfit for consumption, but by the use of a powerful preservative, which arrests further decomposition, it can be made to appear good and sound.

Salicylic acid, for instance, is largely used in the manufacture of jam, and there is no doubt chiefly on account of its property of arresting the fermentation of unsound fruit.

As to the quantities usually added to food, I have found boric acid only in milk, cream, and butter. In butter to the extent of 8 up to 50 gr. per lb., and milk and cream from 6 to 20 gr. per pint.

It is also very largely used for preserving bacon, and a large provision dealer assured me that American bacon is very rarely free from it.\*

Salicylic acid I have found in jam and also in British wine. In jam it has been present to the extent of 2 to 4 grs. per lb., but if it was added to the fruit before boiling a good quantity would probably be lost.

Formalin I have found only in milk and cream, but as there is no reliable method for estimating it in food I have not attempted to do so.

As to colouring matter in food, the most important, I think, is the use of copper for giving a green colour to tinned peas and beans. Most of these come from abroad, chiefly from France and Italy, but they are now being coloured by several English firms. The quantity of copper present is usually from 0.007 per cent. to 0.01 per cent., or about  $\frac{1}{2}$  to  $\frac{2}{3}$  gr. of metallic copper per lb. (but I have on one or two occasions found a larger amount). The usual amount of copper is equal to about 2 to 3 gr. of sulphate of copper per lb. There appears to be a very strong attempt being made to legalise the sale of these articles, for most of the cases taken into court in my district have been defended by the wholesale dealers, often at a considerable expense, but I have obtained convictions in almost all the cases I have had.

Almost all the highest medical opinion in the country appears to consider the use of copper injurious to health; the opinion in Taylor's "Medical Jurisprudence" (p. 315) is as follows: "The quantity of copper contained in such articles may not be sufficient to cause fatal effects, but serious symptoms of gastric irritation are sometimes produced, and in young persons these may assume an alarming character."

\* Boric Acid is also used by butchers, for I received from the Chief Constable of Anglesey a packet of a preservative he found being largely used by a butcher for sprinkling his meat in the hot weather. The packet consisted of boric acid and was labelled "The Universal Food Preserver. To preserve fresh meat, sausages, fish, milk, butter, and various articles of food, sound and sweet in the hottest weather. Prepared by Robert Seager. Ham and Bacon Curer, and Sausage Manufacturer, Ipswich."

Dr. Luff also condemns it: "The employment of copper as an artificial colouring for articles of diet must be regarded as the admixture of a noxious substance, and therefore as rendering the article injurious to health" (Luff's "Forensic Medicine and Toxicology," p. 206), whilst Dr. Lauder Brunton also appears to consider that chronic copper poisoning may be produced: "Chronic copper poisoning is said to have occurred in consequence of the use of copper salts to give a bright green colour to tinned peas and other vegetables, as well as from the employment of imperfectly cleaned copper pans. Some doubt has been thrown on the possibility of producing chronic poisoning by the internal administration of copper in small doses, as in some experiments it was given to animals for a length of time without injury. More recent experiments, however, show that at least in ruminants chronic poisoning may be produced" (Lauder Brunton's "Pharmacology and Therapeutics," p. 666).

These articles are especially injurious to weak persons and children. The reply of the Medical Officer of Health in one of my districts to a question in a case of coppered peas before the magistrate has, I think, a very strong bearing on this point. He was asked by the chairman (a big, strong man) whether these peas would do him (the chairman) any harm, and his reply was "No, very probably they would not do you any harm"; but, turning to another of the magistrates, who was a much older man (who had recently recovered from a severe illness), "but they might kill Mr. B—."

As to the use of other colouring matter, with the exception perhaps of Prussian blue for colouring sweets, I have not found any that I should consider injurious to health. Margarine, of course, is always coloured, and butter occasionally, but I have only found annatto in the samples I have examined, and I do not think that injurious colours are used for this purpose. As to the colouring of margarine, I believe if it was made illegal the sale of this cheap and useful food would be destroyed, for in my opinion margarine is much more wholesome than a large quantity of the old and rancid butter that is used for food; I have frequently had samples of slightly rancid butter brought to me for analysis, as the purchaser thought from the taste and smell that it must be margarine.

Mustard is frequently coloured with turmeric, but except that it is perhaps used to disguise the admixture of a large amount of flour, I do not think there is much objection to it.

The dyeing of sugar is of course a fraud, and is decidedly an adulteration, but I have not had many samples of sugar to examine, and only one that was dyed.

The use of Prussian blue for colouring sweets is, I think, very objectionable, if not dangerous, for it seems probable that the insoluble and non-poisonous cyanides of the colouring matter might possibly, under certain conditions of the digestive organs, be converted into some of the poisonous cyanides. I have not been able to find any information on this point, except that Prussian blue is generally considered non-poisonous. I have frequently found the blue sweets coloured with Prussian blue.

Spirits, especially whisky, are very frequently coloured with caramel.

W. F. LOWE, Assoc. R.S.M., F.I.C.

## APPENDIX No. XVII.

LETTER addressed to Professor THORPE by the Government Analyst of British Guiana, relative to the Tinting of West Indian Sugar.

Dear Dr. Thorpe,

A very representative meeting of proprietors of sugar factories in the West Indies and British Guiana was held yesterday (7th inst.), and it was resolved that steps should be taken to put an end to the use of chloride of tin in the manufacture of so-called Demerara crystals, and orders will be sent out privately and individually to the agents and managers to this effect. As you are aware no cases of injury to human beings have been

reported as having arisen from the presence of minute traces of tin in these sugars, but the universal opinion was that in the light of increased knowledge of the cumulative action of minute traces of metallic salts makers of crystallised raw Demerara sugars would not be justified in continuing the use of such salts.

I remain, dear Dr. Thorpe,

Yours faithfully,

J. B. HARRISON.

20, Talbot Road, Bayswater,  
8th February, 1901.

## APPENDIX No. XVIII.

Appendix.

Handed in by Mr. *Leonard K. Boseley*, as promised on November 17th, 1899.

## LIST of COLOURING MATTERS used in CONFECTIONERY.

| No. | Trade Names.                 | Colours.         | Scientific Names.                                                    |
|-----|------------------------------|------------------|----------------------------------------------------------------------|
| 1   | French Cream Pink, Rhodamine | Reds.            | Hydrochlorate of the phthalein of di-ethyl-meta-amidophenol.         |
| 2   | Concentrated Pink - - - -    |                  | A mixture of hydrochlorate of rosaniline with milk sugar, or starch. |
| 3   | Magenta - - - - -            |                  | Fuchsine, hydrochlorate or acetate of rosaniline.                    |
| 4   | Rhodites - - - - -           |                  | Hydrochlorate of the phthalein of di-ethyl-meta-amidophenol.         |
| 5   | Cherry Red - - - - -         |                  | Sodium salt of tetra-iod-fluoresceine.                               |
| 6   | Ponceau Red - - - - -        |                  | Biebrich or crocein scarlet. Sodium-benzene-naphthol sulphonic acid. |
| 7   | Vermilion - - - - -          |                  | A pure aniline colour.                                               |
| 8   | Rose Red - - - - -           |                  | Purified aniline colour. Guaranteed harmless.                        |
| 9   | Saffron Yellow - - - - -     | Yellows &c.      | <i>Probably</i> the sodium salt of amido-azo-benzene sulphonic acid. |
| 10  | Primrose Yellow - - - - -    |                  | Auramine. (This colour is sold in three grades, 1, 2, and 0.)        |
| 11  | Imperial Yellow - - - - -    |                  | Ammonium or sodium salt of hexanitrodiphenylamine.                   |
| 12  | Citron Orange - - - - -      |                  | The sodium salt of xylene-sulphonic-acid-azo-B-naphthol.             |
| 13  | Chocolate Brown - - - - -    | Brown and Black. | An aniline colour. (No details as to composition.)                   |
| 14  | Jetoline Black - - - - -     |                  | Probably di-amine black.                                             |
| 15  | Heliotrope - - - - -         | Violets.         | Hoffman's violet R, Hydrochlorate of tri-ethyl rosaniline.           |
| 16  | Lavender - - - - -           |                  | A mixture of Hoffman's violet.                                       |
| 17  | Damson Blue - - - - -        |                  | Also a mixture of Hoffman's violet.                                  |

The following colours are also used (Scientific names not given):—Rose paste, Brown paste, Tuscan Orange, and Salmon Pink. The first two are probably mixtures of some of the above-named colours with aluminium hydroxide.

## APPENDIX No. XIX.

Handed in by Mr. *J. Wheeler Bennett*, November 14th, 1899.

(Letter from the High Commissioner for Canada.)

17, Victoria Street,  
London, S.W.  
7 October 1899.

Dear Mr. Wheeler Bennett,

As requested in your letter of the 5th inst., I have much pleasure in giving you below figures relating to the value of bacon and hams exported from Canada to Great Britain for the years 1889-98 —

|      | BACON AND HAMS. | Dollars.  |
|------|-----------------|-----------|
| 1889 | - - - - -       | 380,227   |
| 1890 | - - - - -       | 643,724   |
| 1891 | - - - - -       | 690,210   |
| 1892 | - - - - -       | 1,225,482 |
| 1893 | - - - - -       | 1,960,646 |
| 1894 | - - - - -       | 2,914,778 |
| 1895 | - - - - -       | 3,798,341 |
| 1896 | - - - - -       | 4,370,364 |
| 1897 | - - - - -       | 5,831,623 |
| 1898 | - - - - -       | 8,034,616 |

## Appendix.

The following figures show the value of the export of lard to Great Britain for the same period :—

| LARD. |   |   |   |   | Dollars. |
|-------|---|---|---|---|----------|
| 1889  | - | - | - | - | 10,992   |
| 1890  | - | - | - | - | 6,061    |
| 1891  | - | - | - | - | 1,862    |
| 1892  | - | - | - | - | 2,001    |
| 1893  | - | - | - | - | 65,861   |
| 1894  | - | - | - | - | 75,758   |
| 1895  | - | - | - | - | 103,833  |
| 1896  | - | - | - | - | 11,267   |
| 1897  | - | - | - | - | 14,765   |
| 1898  | - | - | - | - | 18,500   |

And below are given the figures under the heading of "Pork" in the Trade and Navigation Returns of the Dominion, from which, by the way, all these statistics are extracted :—

| PORK. |   |   |   |   | Dollars. |
|-------|---|---|---|---|----------|
| 1889  | - | - | - | - | 906      |
| 1890  | - | - | - | - | 2,922    |

If I can be of any further service to you in the matter please let me know.

Believe me,

Yours faithfully,

J. G. COLMER.

J. Wheeler Bennett, Esq.,  
Hibernia Chambers,  
London Bridge, S.E.

## APPENDIX No. XX.

Handed in by Mr. John Walton Copeman, November 20th, 1899.

(Translation.)

French Ministry of Commerce.

To the President of the French Chamber of Commerce.

In May last you have been good enough to inform me that some "Greened Peas" had been seized in London, and that the seller had had to pay a fine and costs—the peas being reported to contain too much sulphate of copper.

You also informed me of your intention, in conjunction with the British London Chamber of Commerce, to approach the English authorities so as to demonstrate to them that the small quantity of sulphate used in the preparation of preserved peas was perfectly innocuous, and to obtain, if possible, from Parliament the passing of a law fixing the quantity of sulphate allowable in this preparation.

Previous to putting myself in communication on this subject with my colleague, the Minister of Foreign Affairs, I decided to ascertain whether the greened vegetables sent to England did or did not contain a quantity of sulphate superior to that existing in such vegetables used and permitted to be used in France.

I have therefore instructed Mr. Riche, member of the Academy of Medicine, Professor of Mineral Chemistry at the Superior School of Pharmacy in Paris, Director Essayist at the Mint, and at the head of the laboratory of this Ministry, to analyse 19 samples which had been sent to me by your Chamber, by the Syndicate Chamber of "Fabricants des Conserves Alimentaires de Paris," and also had been bought in various shops in this city.

You will observe that the opinion of that chemist is that the proportion of copper found in these various samples does not exceed that which it is permissible to tolerate.

As regards hygiene, the question of the toxicity of copper has been discussed in France in 1860 and in 1869; experts appointed by the law courts, the Council of Public Hygiene of the Seine, and the Consultative Committee of Hygiene in France have examined it repeatedly, and a report of the last-named body stated, on April 15, 1889, that there was no necessity to interdict the then process of greening, and, as a consequence, the Minister of the Interior invited the prefects to annul a circular which previously had been sent out by them preventing the greening of vegetables with copper or copper salts.

A weight of 130 milligrammes of copper to the kilogramme was considered a fair average at the time, whereas, as you will see by Mr. Riche's report, none of the samples he lately analysed, whatever their origin, reach a maximum of 100 milligrammes.

On the other hand, the Paris Chamber of Commerce has affirmed that the use of a small quantity of sulphate of copper in the preparation of preserved vegetables, called "Reverdis" or "À l'Anglaise," is perfectly inoffensive, and cannot be applied to any but fresh vegetables, and by nature green at the time of preparation.

The term "greening" used in trade is incorrect, the process consisting chiefly in the fixing and keeping the normal colour of these vegetables.

The Chambers of Commerce of Bordeaux and L'Orient are also convinced of the perfect innocuity of French preserves prepared with sulphate of copper, and, as a proof, refer to the report of April 15, 1889, and the ministerial circular of April 18, 1889, mentioned as above; they further state that the verdicts given by the French tribunals in favour of the tinning firms are over seven years old, and that ever since not a single accident has occurred.

I therefore beg to inform you that I have especially called the attention of the Minister of Foreign Affairs, my colleague, to the great importance of the question.

I have asked him to invite our ambassador in London to support actively your efforts and those of the British London Chamber of Commerce, so as to obtain from H. M. the Queen's Government that a legislative or legal disposition or decision be obtained to fix the quantity of copper salts allowable in the preserving of vegetables.

Please receive, Mr. the President, &c.,

THE MINISTER OF COMMERCE, INDUSTRY,  
POSTS AND TELEGRAPHS.

Henry Boucher.

(Enclosure to above.)

Report of M. A. Riche.

To the Minister of Commerce, Industry, &c.

Paris, 15 September, 1896.

English law is dumb on the introduction of copper in the preserving of green vegetables so as to maintain their natural colour.

The London French Chamber of Commerce, on the other hand, has reported that many dealers in them in England had been fined for having sold peas greened with copper.

You have given me various samples of greened peas which the above Chamber had sent you for the purpose of ascertaining the proportion of copper they contained.

1. Samples one and two are of Italian origin; three and four are French; five and six are prepared by Frenchmen in England, servants of English companies.
2. To these six samples you have added six others representing, in double, three quantities of ordinary consumption in Paris.
3. Further, I have obtained in five different Paris shops a sample of greened peas.
4. Two tins have already been given me by the firm of Chevalier, of Puteaux.

The following is my analysis of these 19 samples, made in the Ministry of Commerce Laboratory.

**FIRST PARCEL.—Peas sent by the London French Chamber of Commerce.**

| Italian Origin.                                         | 1. Very Fine. | 2. Fine.       |
|---------------------------------------------------------|---------------|----------------|
| Weight of the full tin - - - -                          | 527 grammes.  | 512 grammes.   |
| " strained vegetables - - -                             | 272 "         | 273 "          |
| " copper as compared to 1 kilo. of strained peas.       | 0.085         | 0.100          |
| French Origin.                                          | 3. Very Big.  | 4. Very Big.   |
| Weight of the full tin - - - -                          | 533 grammes.  | 535 grammes.   |
| " strained vegetables - - -                             | 271 "         | 267 "          |
| " copper found as compared to 1 kilo. of strained peas. | 0.090         | 0.085          |
| Prepared in England by Frenchmen.                       | 5. Big.       | 6. Not so Big. |
| Weight of the full tin - - - -                          | 500 grammes.  | 512 grammes.   |
| " strained peas - - - -                                 | 262 "         | 262 "          |
| " copper found as to 1 kilo. of strained peas.          | 0.070         | 0.080          |

**SECOND LOT.—Peas sent by the Paris Syndicate Chamber of Alimentary Products.**

Label.—Appert, 30 Rue de la Moire. Menilmontant.

| —                                              | 1. Small Peas. | 2. Extra Fine. |
|------------------------------------------------|----------------|----------------|
| Weight of the full tin - - - -                 | 557 grammes.   | 550 grammes.   |
| " strained vegetables - - -                    | 315 "          | 310 "          |
| " copper found as to 1 kilo. of strained peas. | 0.100          | 0.090.         |

Label.—Charles Chevalier, Puteaux, Seine.

| —                                              | 1. Small Peas Very Fine. | 2. À l'Anglaise. |
|------------------------------------------------|--------------------------|------------------|
| Weight of the full tin - - - -                 | 525 grammes.             | 515 grammes.     |
| " strained vegetables - - -                    | 275 "                    | 262 "            |
| " copper found as to 1 kilo. of strained peas. | 0.100                    | 0.090.           |

Label.—Lebreton et Bric, Paris.

| —                                              | 1. Small Peas. | 2. À l'Anglais. |
|------------------------------------------------|----------------|-----------------|
| Weight of the full tin - - - -                 | 545 grammes.   | 548 grammes.    |
| " strained vegetables - - -                    | 274 "          | 276 "           |
| " copper found as to 1 kilo. of strained peas. | 0.100          | 0.095.          |

**THIRD LOT.—Small peas bought in Paris shops.**

| Pellier frères, au moins, extra fine, au vert Retouler, 30 Boulevard St. Michael. F. 120 $\frac{1}{2}$ tin. | Small peas very fine à l'Anglaise. Epicurie de Terminus Hotel. F. 125 the full box.              |
|-------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Weight of the full tin - - -                                                                                | 500                                                                                              |
| " strained vegetables - - -                                                                                 | 251                                                                                              |
| " copper found as to 1 kilo. of strained vegetables.                                                        | 0.100                                                                                            |
| Arsene, Sampagnet, Nantes. Petits pois moyens. F. 0.50 $\frac{1}{2}$ tin.                                   | Petits pois extra fine à l'Anglaise. Brand C. C., Place du Havre, 18. F. 1.25 $\frac{1}{2}$ tin. |
| Weight of full tin - - - -                                                                                  | 508                                                                                              |
| " strained vegetables - - -                                                                                 | 261                                                                                              |
| " copper as to 1 kilo. strained.                                                                            | 0.100                                                                                            |

Conserves alimentaires de choix, Pois moyens.

Retailer: Olida me Drouot, F. 0.50.

Weight of full tin, 512 grammes.

Weight of strained vegetables, 247 grammes.

Weight of copper found as to 1 kilo. strained, 0.090.

**FOURTH LOT.—Peas sent by Chevalier.**

Petits pois, very fine, à l'Anglaise.

| —                                         | 1.           | 2.           |
|-------------------------------------------|--------------|--------------|
| Weight of full tin - - - -                | 523 grammes. | 519 grammes. |
| " strained vegetables - - -               | 273 "        | 271 "        |
| " copper found as to 1 kilo. of strained. | 0.090        | 0.085.       |

The proportion of copper in all these is extremely regular, since it oscillates, in the 19 samples, between 80 and 100 milligrammes of metal per kilogramme of strained peas, which corresponds to 320 to 390 milligrammes of sulphate of copper, should this salt be used in the greening process, which is, we may say, always the case.

Does this proportion of copper exceed that which it is well to tolerate?

No, in the point of view of the manufacturer, as peas thus greened resemble in a remarkable manner the natural green peas.

No, either, in a hygienic point of view. This question of toxicity of copper has been fully discussed in France from 1860 to 1869, various scientific bodies have studied it at various times, and in all its features, the history of which would be too long for me to enter into. It was closed in fact by the report of the Consultative Committee of Hygiene, 15th April, 1889, which declared that there was no occasion of interdicting the method of greening vegetables with copper salts.

And as a consequence of this report the Minister of the Interior authorised all prefects to repeal their circulars bearing on the subject, which in Paris was done by the Prefect of Police on May 7th, 1889.

The process approved of by the Consultative Committee is exactly that followed by all tanners, which fact is confirmed by the reporter on Mr. Ogier's analysis in the following words:

Amongst the facts supplied by Mr. Ogier, it is well to note that the dose of metallic copper found in greened vegetables is about 13 milligrammes per 100 grammes, viz., 130 milligrammes per kilo.; that with a dose of 10 milligrammes, viz., 100 milligrammes per kilo., they are well greened, and that with a dose of 40 milligrammes, viz., 400 milligrammes per kilo., they have a decided taste of sulphate of copper, which renders them uneatable.

One will notice that none of the 19 samples analysed by me as above reach 130 milligrammes of copper to the kilogramme, which figure, however, is considered safe by the Committee.

Experiments which have proved the innocuity of greened vegetables with copper emanate from various savants, well known men, and under the most varied conditions.

Appendix.

Many have been made on animals, others on men. Mr. Galippe, after experimenting on himself, has not hesitated in using for many months, for himself and for the whole of his family, vegetables cooked and preserved in copper basins.

It has been asked if vegetables greened with copper, though not toxique, were not likely to interfere with digestion. This is not likely, as copper salts—sulphate, acetate, are soluble in water, and the copper fixed on vegetables is found to be in an insoluble form, since the water which contains them hardly shows any trace of them.

Copper exists there in a state of combination, ill-defined and stable, which probably does not attack, or attacks with great difficulty the liquids in human economy.

Messrs. Petit and Sley have made experiments on this point, 2 grammes of sulphate of copper dissolved in 40 c.c. of distilled water have been added to 60 c.c. of gastric juice, in which have been placed 20 grammes of blood fibrine; the whole has been kept in a condenser at 45° for 18 hours. Result: the fibrine was entirely dissolved.

Mr. Ogier has prepared in his laboratory peas and beans in the natural state, also some greened with copper;

the proportion of copper varied from 10,100 and 740 milligrammes per kilo. of vegetables. He has then submitted both, under similar conditions, to experiments on digestibility with pepsine maceration of calf's stomach, pomegranate juice. The digestibility of both has been identical.

Let us add that no trace of accident due to copper has ever been found in persons eating cacao or chocolate, a food which, according to Duclaux, contains notable proportions of copper, indeed sometimes superior to that introduced in greened vegetables.

Conclusions: Owing to our analysis of the 19 samples of greened peas as above, it is rational to conclude that the consumption of peas, greened with copper as per actual process, does not offer any danger to public health.

A. RICHE,

Member of the Academy of Medicine; Professor of Mineral Chemistry at the Paris Superior School of Pharmacy; Director of the Ministry of Commerce Laboratory.

## Appendix.

## APPENDIX No. XXIV.

Handed in by Dr. Samuel Rideal on January 15th, 1900.

The Time Milk is kept sweet by the addition of 1 : 2,000 of Boric Acid, or 1 : 50,000 of Formaldehyde at Various Temperatures.

In order to ascertain this, quantities of fresh milk, containing (1) 1 : 2,000 of boric acid; (2) 1 : 50,000 of formaldehyde; (3) control, were measured into balloon flasks and loosely plugged with cotton wool. These sets were then incubated at the following temperatures, 13 C., 18 C., and 24 C. (as representing approximately winter, medium, and summer temperatures), and 25 c.c. taken out from each and titrated every few hours with decinormal soda, using phenol-phthalein as an indicator, the total acidity being calculated to lactic acid (1 c.c. N/10 soda = '009 gramme of lactic acid). The original milk at starting required 5 c.c. N/10 soda per 25 c.c., corresponding to 0.18 per cent. of lactic acid.

| PER CENT. LACTIC ACID. |                    |                  |                    |
|------------------------|--------------------|------------------|--------------------|
|                        | 13 C.<br>(55.4 F.) | 18 C.<br>(64 F.) | 24 C.<br>(75.2 F.) |
| 15 hours :             |                    |                  |                    |
| Blank - - - -          | 0.18               | 0.20             | 0.28               |
| Boric acid - - -       | 0.18               | 0.18             | 0.22               |
| Formaldehyde - -       | 0.18               | 0.18             | 0.19               |
| 20 hours :             |                    |                  |                    |
| Blank - - - -          | 0.18               | 0.20             | 0.24               |
| Boric acid - - -       | 0.18               | 0.20             | 0.22               |
| Formaldehyde - -       | 0.18               | 0.18             | 0.20               |
| 23 hours :             |                    |                  |                    |
| Blank - - - -          | 0.18               | 0.21             | 0.28               |
| Boric acid - - -       | 0.18               | 0.18             | 0.24               |
| Formaldehyde - -       | 0.18               | 0.18             | 0.22               |
| 39 hours :             |                    |                  |                    |
| Blank - - - -          | 0.19               | 0.39             | 0.80               |
| Boric acid - - -       | 0.18               | 0.26             | 0.65               |
| Formaldehyde - -       | 0.17               | 0.21             | 0.59               |

From these results it will be noticed that at the lowest temperature, viz., 13° C., even after 39 hours there is no increase in the acidity of the milks containing boric acid and formaldehyde, the actual titrations recording a

slightly lower amount of lactic acid. In these two milks at 18 C. there is no appreciable rise in the acidity till after 23 hours incubation. In considering the results at 24 C. the question as to what maximum acidity can be allowed to milk without its being pronounced sour is raised.

Thorner (Chem. Zeit., 1891, p. 1108) has investigated the acidity requisite to coagulate milk. Titrating under similar conditions to the above, he found that milk coagulated on warming when the acidity reaches 22 (c.c. N/10 soda per 100 c.c. of milk), corresponding to 0.207 per cent. of lactic acid. I have found the coagulating point somewhat higher than this. Normal milk was incubated at 22 C., and every few hours a fraction was removed and tested by heating to 100 C. for five minutes and also by pouring some of the milk into boiling water, the acidity being determined at the same time.

| Number of Hours. | Degree of Acidity. | Per Cent. of Lactic Acid. | Coagulation Tests.                                       |
|------------------|--------------------|---------------------------|----------------------------------------------------------|
| 1                | 18                 | 0.162                     | Both tests negative.                                     |
| 4                | 19                 | 0.171                     | - - ditto.                                               |
| 6                | 19.2               | 0.173                     | - - ditto.                                               |
| 8                | 19.6               | 0.176                     | - - ditto.                                               |
| 11               | 20.4               | 0.184                     | - - ditto.                                               |
| 15               | 23                 | 0.252                     | Coagulated at 100 C., but not by pouring into hot water. |

Therefore, when the acidity exceeds 0.25 per cent. lactic acid, the milk would be considered sour and unfit for sale. And taking this as the maximum acidity allowable, it will be seen from the previous table that in all cases the milk has been kept sweet by the 1 : 2,000 boric acid, and 1 : 50,000 of formaldehyde over the 23 hours.

In repeating this experiment, with a milk incubated at 18 C., it was found that when the acidity was equal to 25.6 degrees, or 0.230 per cent. of lactic acid, the milk was sufficiently acid to cause a slight coagulation on heating on the water-bath. It will therefore be seen that Thorner's limit of 0.207 per cent. of lactic acid is rather too low, and that from 0.23 to 0.25 per cent. of lactic acid is the limit which may be regarded as safe for dietetic purposes.

## APPENDIX No. XXV.

Handed in by Major Charles E. Cassal, January 15th, 1900.

## (1.)

EXTRACTS from the Annual Report of Charles E. Cassal, F.I.C., the Public Analyst for the Parish of Kensington, for the year ended 31st March, 1891.

15. The addition of boric acid preparations to milk is a matter upon which special reports have been made at the request of your vestry. It has been stated that proceedings might be taken under the 3rd Section of the Sale of Food and Drugs Act, 1875. Proceedings might be taken under the 6th Section of that Act and the 2nd Section of the Amendment Act of 1879, inasmuch as milk containing boric acid may be regarded as not of the "quality" of milk demanded by the purchaser, the proof of defect in the quality of an article being sufficient for action to be taken, whatever views may be held as to what constitutes legal defects in the "nature" and "substance" of such article. The 6th Section provides that an offence shall be deemed to be committed if an article is not of the nature, substance, and quality de-

manded by the purchaser; the 2nd Section of the Amendment Act provides that it is not incumbent on the prosecution to prove defects in all these three respects. Defect in any one is sufficient. No offence under this section, however, is committed "where any matter or ingredient not injurious to health has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce, in a state fit for carriage or consumption, and not fraudulently to increase the bulk, weight, or measure of the food or drug, or conceal the inferior quality thereof." It may, however, be contended that the admixture is not required for preservation in course of transit, as when this is necessary there are other, although more expensive, means (i.e., refrigeration) of accomplishing the object; and it may further be held that it does enable the inferior quality of a milk to be concealed, as the practice allows of stale milk being sold as fresh or new milk.

16. Your vestry decided to ask for the opinions of Sir

Andrew Clark, M.D., Sir Henry Thompson and Dr. Lauder Brunton, with respect to the admixture of boracic acid and its compounds with articles of food. The replies of these gentlemen were entered upon the minutes of the vestry. Sir Andrew Clark, while regretting his inability to take part in any special enquiry, made the following remarks:—"Seeing that chemical compounds are now widely employed in the preparation and preservation of foods, knowing that many of them, although innocuous in small occasional doses, become in small doses continued over long periods destructive to health; and, furthermore, believing that many obscure and incurable disorders are begotten in this manner, I regard the enquiry proposed by your vestry as one of the greatest importance to the well-being of the community; and certain, if successfully completed, to prove of great public advantage."

Sir Henry Thompson remarked that, technically, the addition of preservatives must be regarded, more or less, as constituting an adulteration; that there was no doubt, on the authority of physicians in Germany and in this country, that boric acid in what was called "full doses" was an irritant to the digestive organs, but that it by no means followed that a small quantity should exercise any evil influence whatever. He was of opinion that a quantity of eight or ten grains to the pint of milk, the amount generally used, would not be injurious to the adult who consumed, say, a pint daily—an ample allowance; but that, on the other hand, the infant, who was a large consumer of milk, was also much more liable to injury by the admixture of boric acid, being far more susceptible than the adult to the influence of all chemical agents. The proportion named "would be calculated to be injurious when taken habitually, certainly to children under three or four years of age."

Taking all the facts cited into consideration, Sir Henry Thompson was "disposed to believe that the employment of a small proportion of boric acid might be permitted in the milk trade with advantage to the consumer, on the following conditions":—(1). "A declaration should be required respecting all milk and cream offered for sale, whether or no any boric acid or other agent has been added thereto for the purpose of preserving it." (2). "A precise statement should be made upon a label bearing also the name of the salesman, to be affixed to all vessels containing milk or cream offered for sale, naming the preservative agent employed, and the quantity added per pint." (3). "When milk or cream thus 'preserved' is sold 'on draught,' a ticket should be supplied to the purchaser, containing the information furnished by the label above named." (4). "When specimens thus certified and sold are proved by analysis to contain a notably larger quantity than that named on the ticket or label, or when specimens declared to be free from admixture with any chemical agent are found to contain one, the salesman should be proceeded against for selling milk which is adulterated, knowing it to be so. Such regulations would ensure to each individual who might desire to exercise his own judgment on this matter the opportunity of doing so."

Sir Henry Thompson also pointed out that remarks made with regard to boracic acid might be held to apply to borax also.

Dr. Lauder Brunton considered the question to be a particularly difficult one, and was uncertain what to say regarding it. He stated that he had no personal experience in the matter of the use of boracic acid, and that such information as he would be able to afford the vestry would be necessarily derived from books. Upon this authority he stated that it was "known to be a poison in large doses" and had "also been found to be injurious when added to foods."

(2.)

#### BORIC ACID IN BUTTER.

EXTRACTS from the Annual Report of Charles E. Cassal, F.I.C., the Public Analyst for the Parish of Kensington, for the year ended 31st March, 1893.

Letter from the Vestry Clerk of Kensington to the Secretary of the Local Government Board.

Town Hall, Kensington,

Sir,

16th May, 1893.

I HAVE been directed by the Vestry of Kensington to bring under the notice of the Local Government Board the extract which appears in the enclosed report of the public analyst of this parish dealing with the question of whether samples of butter found to contain boric acid preservatives should or should not be reported as adulterated.

3017.

From such extract it will be seen by the Board that the percentage of adulteration in this parish is appreciably increased, owing to our public analyst holding the opinion that he has no option, in drawing up his statutory report, but to return samples of butter containing boric acid as adulterated, and this view my vestry have no desire to combat. They, however, learn that some of the public analysts report such samples as genuine, and this being so, the vestry feel that by reason of the difference of views which appears to prevail among the public analysts, this parish, and those parishes and districts whose public analysts act in accord with ours, are prejudicially affected as regards the comparisons which may be drawn from the abstracts of reports of public analysts which are published in the annual report of the Local Government Board.

The vestry accordingly deem it expedient to seek some direction at the hands of the Board upon the point, and to request that the Board will state whether samples of butter containing boric acid for preservative purposes should be returned in the statutory report of the public analyst as adulterated or genuine, so that uniformity of procedure may prevail throughout the parishes and districts in which the Sale of Food and Drugs Acts are enforced.

I have the honour to be, sir,

Your obedient servant,

(Signed) Wm. Chambers Leete,  
Vestry Clerk.

The Secretary, Local Government Board,  
Whitehall, S.W.

To this letter the following reply was received:—  
[Copy of Reply].

Local Government Board, Whitehall, S.W.  
25th May, 1893.

Sir,

I am directed by the Local Government Board to acknowledge the receipt of your letter of the 16th instant, enquiring on behalf of the vestry of the Parish of St. Mary Abbotts, Kensington, whether butter found to contain boric acid for preservative purposes should or should not be reported as adulterated.

I am to state that the question is one which the Board have no authority to decide, but they may refer the vestry to note (d) appended to the form of certificate in the schedule to the Sale of Food and Drugs Act, 1875, which authorises the analyst to insert at his discretion his opinion whether any mixture was for the purpose of preserving the article, and whether it was excessive. I am also to refer to the remarks on the subject at page 6 of the enclosed extract from the board's report for 1890-91.

I am, sir,

Your obedient servant,

(Signed) Alfred D. Adrian,  
Assistant Secretary.

To W. C. Leete, Esq., Clerk to the Vestry of the Parish of St. Mary Abbotts, Kensington.

20. The following are the remarks in the extract from the Board's report alluded to in the above letter, the italics being mine to show the more important points:—

"It may be noted that the use of boric and boracic acids as preservatives of butter and other substances liable to decompose speedily seems to be finding increased favour among dealers, and is at the same time creating a difficulty for analysts, since it is not always clear in what cases the addition may come within the proviso of section 6 of the Sale of Food and Drugs Act, 1875, with regard to 'any matter or ingredient not injurious to health' which 'has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce, in a state fit for carriage or consumption.' *There is no doubt that boric or boracic acid, if taken in large quantities, would be injurious to health, but we have no sufficient information to show whether such minute amounts as are generally added as preservatives could be regarded as having that effect, and more exact information is wanted before it can be decided whether a process which prima facie may be regarded as intended to prevent the loss of valuable food, must be held to be prohibited by law.*"

21. The present attitude\* of the Local Government Board on the subject, at any rate with respect to butter,

\* i.e., in 1893.—C. E. C.

Appendix. is made perfectly plain by the reply of the Board to the vestry's letter and by the extract quoted. While adhering, therefore, to my previously-expressed opinion that the *unacknowledged* presence of boric acid preparations in food constitutes adulteration, I shall feel justified, in future, in classifying samples of butter containing boric acid only as "genuine," and in merely reporting the presence of that substance when it is found to have been added.

(3.)

EXTRACT from the Quarterly Report of the Public Analyst for St. George, Hanover Square, for the quarter ended on the 31st December, 1896.

## PRESERVED PEAS.

The six samples submitted were all found to contain copper and were reported as adulterated. The particulars relating to these samples are as understated:—

| Sample. | On the Sample as submitted. |                          |                                      | On desiccated Sample. |                          |
|---------|-----------------------------|--------------------------|--------------------------------------|-----------------------|--------------------------|
|         | Copper per cent.            | Copper grains per pound. | Sulphate of Copper Grains per pound. | Copper per cent.      | Copper grains per pound. |
| A.      | 0.006                       | 0.422                    | 1.664                                | 0.0714                | 4.996                    |
| B.      | 0.0038                      | 0.267                    | 1.054                                | 0.0365                | 2.56                     |
| C.      | 0.0035                      | 0.596                    | 2.35                                 | 0.0997                | 6.98                     |
| D.      | 0.008                       | 0.562                    | 2.216                                | 0.0836                | 5.85                     |
| E.      | 0.0067                      | 0.469                    | 1.84                                 | 0.0532                | 3.72                     |
| F.      | 0.0085                      | 0.593                    | 2.336                                | 0.0564                | 3.95                     |

The attention of authorities concerned with the administration of the Food and Drugs Acts has recently been again directed to the presence of copper in preserved vegetables by a successful prosecution at the instance of the Board of Works for the St. Saviour's District, Southwark. A report of this case was forwarded to the vestry, and was considered by the Sale of Food and Drugs Acts Committee. As stated in the report referred to, there is no doubt that "the practice of colouring bottled peas by the addition of a salt of copper—usually the sulphate—is attended with injurious effects"; that "in most countries the practice is forbidden," and that "the recognised English text-books on poisons, medical jurisprudence, and foods are practically unanimous in their censure of the practice of adding the salt of copper for the purpose of imparting a fresh or bright green colour to the peas." It appears that as long ago as 1877 a vendor was convicted at the Marlborough Street Police Court for selling peas containing copper, and that other convictions have been secured since at Liverpool, Bradford, and Edmonton. In the case here referred to the magistrate convicted the vendor. The latter appealed, and after a protracted hearing at the Sessions before Mr. Soames, the Deputy-Chairman, when a number of witnesses were examined on both sides, the appeal was dismissed, and the conviction was confirmed with costs.

(4.)

EXTRACT from the Annual Report of the Public Analyst for St. George, Hanover Square, for the year ended on 31st March, 1890.

Two samples of sweets were reported as adulterated. The first consisted of differently coloured balls, about half an inch in diameter. Among them were several of a brown colour. These were found to contain oxide of iron in the average proportion of 2.4 milligrammes of oxide per ball, and a mean percentage of 0.212 oxide by weight on the brown balls.

The second sample consisted of small brown and black balls, and was obtained by direction of the committee, upon the advice of the vestry's solicitors, from the same vendor who had supplied the first sample. This sample was reported as containing oxide of iron, silica and sand, and charcoal, as follows:—

Oxide of iron 0.227 per cent. on the brown balls.

Silica and sand 0.185

Charcoal 0.2 per cent. on the black balls.

The use of a compound of iron as a colouring material for sweets is objectionable; such compounds might prove injurious, and no insoluble matters such as charcoal and sand should be contained in sweets in any appreciable amounts, unless (in the special case of charcoal) the fact of the admixture is stated in the name of the article.

The vendors and manufacturers of these samples were cautioned by direction of the vestry.

(5.)

EXTRACT from the Annual Report of the Public Analyst for St. George, Hanover Square, for the year ended on 31st March, 1898.

Sweets containing oxide of iron and earthy matter.—Of the three samples of sweets reported as adulterated two contained ferruginous earthy matter insoluble in water in sufficient amount to constitute adulteration within the meaning of the Acts. The particulars relating to these samples are as understated:—

(a) 0.806 per cent. ferruginous earthy matter insoluble in water, of which 42.18 per cent. consisted of oxide of iron (0.34 per cent. of oxide of iron in the sweets).\*

(b) 0.851 per cent. of ferruginous earthy matter insoluble in water, of which 47.5 per cent. consisted of oxide of iron (0.405 per cent. of oxide of iron in the sweets).†

The first-named sample (a) was described as "Aniseed Balls"; the second (b) as "Caramel Beans."

A purchaser asking for "Sweets," and getting such articles as those above described, must be regarded as "prejudiced" on account of the presence of the insoluble earthy matter, and on account of the fact that the oxide of iron, present in the amounts certified, through its medicinal action is objectionable for a healthy person, and may be injurious, especially to young children, if not taken under medical direction. The Medical Officer of Health, Dr. Corfield, having been consulted prior to the institution of proceedings against the vendor of sample (a), adopted this view of the matter, and gave evidence in accordance therewith at the hearing of the case.

(6.)

EXPERIMENTS with Solutions of Formaldehyde ("Formalin") carried out by Charles E. Cassal, F.I.C.

1. Shreds of gelatin were soaked in water until soft, and were placed in the following solutions of formalin (the formalin containing about 40 per cent. of formaldehyde).

(a) 0.5 per cent. formalin.

(b) 0.1 per cent. formalin.

(c) 0.01 per cent. formalin.

With all three solutions a marked effect is immediately produced. In one hour in the cases of solutions (a) and (b) the gelatin had become absolutely insoluble in boiling water, and was converted into a hard substance resembling brittle horn. In the case of solution (c) the same effects were produced after a somewhat longer time—i.e., absolute insolubility and conversion into the horny condition.

2. Fresh egg albumen treated with the above mentioned solutions was converted into a gelatinous mass insoluble in cold water.

3. Digestion experiments, with Armour's pepsine and hydrochloric acid:—

(a) 1 gramme fibrin, 0.05 gramme pepsine, 50 cubic centimetres of water, acidified with hydrochloric acid; and formalin in the proportion of 0.01 per cent. on the mixture (1 in 10,000).

(b) Same preparation as (a), but without formalin.

Both kept at a temperature of 104° F.

After 2½ hours the fibrin in (b) had dissolved.

After 6 hours the fibrin in (a) had not dissolved, and an insoluble mass had settled at the bottom of the flasks.

(d) 5 grammes coagulated and comminuted egg albumen, 50 cubic centimetres of water, 0.0055 gramme pepsine, 0.4 cubic centimetre hydrochloric acid; and formalin in the proportion of 0.01 per cent. on the mixture (1 in 10,000).

(e) Same preparation as (d), but without formalin.

\* Vendor convicted, and fined 2s. 6d. and 2s. costs.

† Vendor convicted, and fined 5s. and 12s. 6d. costs.

Both kept at a temperature of 104° F.

After 2½ hours the albumen in (e) had dissolved.

After 6 hours the albumen in (d) had not dissolved. There was an insoluble deposit at the bottom of the flasks.

(f) Experiments with milk. Five cubic centimetres of milk, 50 cubic centimetres of water, 0.4 c.c. Hydrochloric acid, 0.0066 gramme pepsine, and formalin in proportion of 0.01 per cent. on the mixture.

(g) Same preparation as (f), but without formalin.

A number of similar experiments to the above were made with different quantities of milk.

The effects in these experiments were difficult to observe; but the differences between the preparations containing formalin and those free from it were quite obvious. In the preparations without formalin the curd gradually passed into solution. In the preparations containing formalin the separated curd was granular, or in hardened clots, and was plainly very difficult, if not incapable, of solution. C. E. C.

(9.)

EXTRACTS from the Annual Report of the Public Analyst for St. George, Hanover Square, for the year ended on the 31st March, 1896.

#### "BRITISH WINE" CONTAINING SALICYLIC ACID.

The three samples of so-called "British Wines" reported as adulterated contained salicylic acid in the proportions which are understated:—

(a) "Orange Wine," 26.6 grains per gallon of salicylic acid.

(b) "British Sherry Wine," 11.55 grains per gallon of salicylic acid.

(c) "Black Currant Wine," 4.0 grains per gallon of salicylic acid.

Appendix.

The remaining samples of "British Wines," consisting of three samples of "Ginger Wine," two of "Orange Wine," one of "Elder Wine," and one of "Raisin Wine," were free from salicylic acid and other chemical preservatives, and were reported as having the composition of samples which must be regarded as unadulterated, and, under existing circumstances, as not sold "to the prejudice of the purchaser," and therefore as genuine.

The vendors of the samples marked (a) and (b) were summoned by the Vestry, and in the result the summonses were dismissed.

The cases were heard by Mr. De Rutzen, at the Westminster Police Court, on the 6th November, 1895, that of the sample containing 26.6 grains per gallon of salicylic acid being taken first, and as governing the other case. Evidence in support of the Vestry's case was given by your Medical Officer of Health (Dr. Corfield) and by myself; the principal points put forward being, from the medical point of view, that salicylic acid was a potent drug, that even in very small doses its continued use would be injurious to health, and that its presence in a food in quantity sufficient to produce its specific antiseptic or "preservative" effect on that food, would, from that fact, affect the normal process of healthy digestion, and would be injurious to health. From the more strictly chemical and technical point of view the Vestry's evidence showed that salicylic acid could not be called a component part of a genuine "British Wine," that its addition was not necessary for the purpose of producing a sound and good article which would keep, that the addition of the acid might serve the purpose of concealing the inferior quality of the article or of the materials used to make it, and that, when the sample in question was analysed, seven other samples of "British Wines" were also analysed, and were found to be free from salicylic acid, and from other "chemical preservatives." A large number of witnesses were called for the defence. In this report it is unnecessary to enter into an examination of the fitness of some of these witnesses to give evidence upon such a subject, nor is it necessary to criticise the value of that evidence. It will be sufficient to state that the evidence given by the witnesses for the defence was mainly to the effect that, in their view, the presence of salicylic acid in the amount certified was not injurious to health, and that it was a necessary addition.

The magistrate reserved his decision, and on the 6th January delivered judgment in favour of the defendants, and dismissed the summonses in both cases, but without costs. In the course of his judgment Mr. De Rutzen observed that the only witness called to corroborate the view of the Public Analyst was Dr. Corfield. He came to the conclusion that the summonses should be dismissed on the ground that the salicylic acid present was not proved to be injurious to health, and that it was not proved to his satisfaction that it was not required for the production of the article in a fit state for consumption; the cases coming therefore, according to the evidence given, within the first proviso of the 6th section of the Sale of Food and Drugs Act.

It may be well to point out that this judgment only affects these particular cases, and that the Vestry are not precluded from again taking action in similar cases, and bringing forward additional evidence in support of them.

In commenting upon the cases, the *British Medical Journal*, the organ of the British Medical Association, made the following remarks among others: "Salicylic acid is a poison." "It is no sufficient answer to accusations under section 6 of the Sale of Food and Drugs Act to prove that single large doses of a particular addition have been taken by a number of persons without injury." "They" (antiseptics) "should be absolutely prohibited unless a label be placed upon everything sold after being thus treated." In a further article the *British Medical Journal* observes: "We believe that Dr. Corfield, in saying that the long-continued use of small doses of this powerful drug may be injurious to health, has on his side the support of medical experience and opinion. The decision is greatly to be regretted in the interests of public health."

## APPENDIX No. XXVI.

Handed in by Mr. *Harald Faber*, as promised on Tuesday, January 16th, 1900.

APPENDIX 2, to the Report from the Committee (Landstinget), on the Manufacture and Sale of Margarine Bill, 15th February, 1896 (abbreviated).

The Royal Laboratory for Agricultural Research,  
Copenhagen, 20th January, 1896.

REPORT on Experiments to Test the Keeping of  
Fresh Butter.

The samples of butter were procured from Kildedyb Co-operative Dairy, near Kolding; some of them were made without the addition of salt or any other preservative, while to some was added "Preservitas," the preservative mostly used, and containing 47·8 per cent. of boracic acid, 8·6 of saltpetre, 11·1 of chloride of potassium, and to others varying amounts of pure saltpetre.

Before it was decided to have the butter made at Kildedyb Dairy, it had been ascertained that the butter of that dairy was of excellent quality, and that the working of the dairy in every respect was up to date, especially as far as the production of butter free from salt was concerned, and there was therefore no reason to make any alteration in the daily working for the purpose of producing the butter intended for the experiment. The cream was pasteurised at 70° C. The dairy manager supervised the churning, &c., and every day, when butter was required for testing, he took out of the same churning four samples of about 25lbs. each. The preservatives were added during the first working of the butter.

[The butter was made on the 28th, 29th, and 30th December last year, and on the 3rd and 4th January this year. Assistants from the laboratory supervised the making, packing, and marking of the different samples.]

The butter was judged by the three particularly able butter merchants who during several years have assisted at a number of scientific judgments of butter at the laboratory. The samples were judged first time on the 7th January, second time on the 14th January, and third time on the 21st January. At each judging every judge examined all the samples independently, and gave each sample points according to the scale generally used at the State butter shows at the laboratory (Foreign Office, 1889, Miscellaneous Series, No. 151), where 15 points denotes the very finest butter, and 0 points the most inferior quality. Afterwards all three judges went over the samples together to decide finally the number of points to be given to each sample. These points for each of the three judgments of the four

samples from each of the five days of manufacture are given in the table attached:—

|                | Nothing added. |     |     | ½ per Cent. Preservitas. |     |     | 1 per Cent. Preservitas. |     |     | Saltpetre. |     |     | Amount of Saltpetre added. |
|----------------|----------------|-----|-----|--------------------------|-----|-----|--------------------------|-----|-----|------------|-----|-----|----------------------------|
|                | 1.             | 2.  | 3.  | 1.                       | 2.  | 3.  | 1.                       | 2.  | 3.  | 1.         | 2.  | 3.  |                            |
| 1895:          |                |     |     |                          |     |     |                          |     |     |            |     |     | Per Cent.                  |

| " 29           | 12             | 10  | 9   | 12                       | 10  | 9   | 12                       | 10  | 9   | 12         | 9   | 9   | ½                          |
| " 30           | 11             | 8   | 9   | 11                       | 8   | 9   | 11                       | 9   | 9   | 11         | 8   | 9   | ½                          |
| 1896:          |                |     |     |                          |     |     |                          |     |     |            |     |     |                            |
| Jan. 3         | 12             | 9   | 8   | 12                       | 9   | 8   | 12                       | 10  | 8   | 12         | 9   | 8   | ½                          |
| " 4            | 11             | 10  | 8   | 11                       | 10  | 9   | 11                       | 9   | 9   | 11         | 9   | 8   | ½                          |
| Average Points | 11·2           | 9·0 | 8·2 | 11·4                     | 9·2 | 8·6 | 11·4                     | 9·4 | 8·6 | 11·2       | 8·8 | 8·6 | —                          |

The points obtained at the first judging show that the butter was fine. It is quite an exception for the judges at the State butter shows to give higher points than 12, which number of points therefore practically denotes extra fine quality. The points given at the second and third judging show how the different samples have kept. The greater the difference in points obtained at the subsequent judging the less has been the keeping quality of the butter. Dealing with the average points for the butter from all five days of manufacture the following has been the reduction in points:—

|                         | From 1st to 2nd judging. | From 2nd to 3rd judging. | From 1st to 3rd judging. |
|-------------------------|--------------------------|--------------------------|--------------------------|
| Nothing added           | 2·2                      | 0·8                      | 3·0                      |
| ½ per cent. Preservitas | 2·2                      | 0·6                      | 2·8                      |
| 1 per cent. Preservitas | 2·0                      | 0·8                      | 2·8                      |
| ½-1 per cent. Saltpetre | 2·4                      | 0·2                      | 2·6                      |

Nothing striking is revealed by these figures. The butter to which "Preservitas" was added has averagely lost about the same number of points from one judging to the next, as the butter to which nothing had been added. The addition of pure saltpetre seems to have caused a slightly smaller total loss between the first and third judging (seems to have kept the butter better), the difference, however, being very small.

[Reservation is taken as to drawing too general conclusions from this somewhat limited investigation.]

## APPENDIX No. XXVII.

Handed in by Mr. *Harald Faber*, as promised on January 16th, 1900.

The director of the official laboratory for the examination of foods at Copenhagen having applied to the Minister of Justice with regard to the increasing use in food of preservatives, especially boracic acid and salts thereof and salicylic acid, the Minister requested the Royal Board of Health to express an opinion on the effect on health of the use of these chemicals in food, when the Royal Board of Health, in a communication to the Minister of Justice, dated 29th October, 1895, gave it as their opinion :

“That the use in food of boracic acid and salts thereof may have an injurious effect on health when an amount of one gramme of boracic acid, or even less, is thereby daily introduced into the organism for a considerable time ;

“That the addition of boracic acid (and salts thereof) to foods for infants, especially milk, even in proportionally small amounts, may be dangerous ;

“That the use in food of salicylic acid and compounds thereof ought to be prohibited on account of their injurious effect on health.”

When the law of 1894 on the official examination of foods enacted only for three years, came to the Rigsdag for revision, the Minister of Justice, during the session 1896-97, proposed the following addition to sect. 5 :

“The Minister of Justice may, by decree, prohibit the addition to food intended for sale of such

chemicals which, even if they be not immediately harmful, still may by continued consumption have an injurious effect on the health of the consumer.”

This passus, however, was struck off the Bill.

In the Margarine Law of 1897 it is enacted, in sect. 10 :

“The addition to butter and margarine, intended for sale, of any other preservative than common salt is prohibited; it is likewise prohibited to import, export, carry in transit or deal in butter and margarine containing any other preservative than common salt.”

When this provision of the law was introduced it was explained that a similar prohibition was already found in the Belgian Law of 11th March, 1895, that the question was being discussed in Germany, Sweden, and Great Britain, that the use of preservatives was general in Australian butter, but that its effect on the health of the consumer was questionable, that no other preservative than salt was at the time used in Danish dairies, and that it was declared by experts and found at the State Butter Shows that well-made butter needed no preservatives.

In a Bill recently introduced in the Rigsdag it is proposed that :

The Minister of Agriculture may prohibit the sale and export of meat, and foods prepared from meat, containing chemicals which may be injurious to health.

## Appendix:

## APPENDIX No. XXVIII.

HANDED in by Mr. *W. Collingwood Williams*, as promised on January 19th, 1900.

Year 1899.

| The Five County Boroughs in the West Riding of Yorkshire. | 176                                                                             | 154                                           | 147                               | 239                              | 165                               |
| West Riding Administrative County                         | 154                                                                             | 145                                           | 139                               | 171                              | 161                               |

It can also be shown, from the detailed records of the same period, that, while the excessive infantile mortality of the Third Quarters became relatively greater in the later years of the period, there was an improvement in the First and Second Quarters.

## APPENDIX No. XXXI.

Handed in by Mr. H. Droop Richmond, on Monday, January 22nd, 1900.

DETAILED ANALYSIS of COMMERCIAL PRESERVATIVE which have come directly under the notice of the Aylesbury Dairy Company, Limited.

|                          | TIME IN HOURS.                        |      |               |        |        |
| 60*                      | 34                                    | 60   | 10            | 50     | 90     |
| 70                       | 9                                     | 20   | 6             | 24     | 58     |
| 80                       | 4                                     | 14   | 7             | 18     | 44     |
| 90                       | 3                                     | 12   | 3             | 16     | 37     |
| 100*                     | 3                                     | 14   | 2             | 18     | 35     |

\* The values at these temperatures were obtained by extrapolation.

It is assumed that milk turns sour when an increase of the acidity of 25° has taken place (i.e., 100 c.c. of milk require 25 c.c. more N/10 soda solution to neutralise to phenolphthalein than when quite fresh).

It is assumed that, to be of any appreciable use, preservative should increase the "life" of the milk by 12 hours at 80°–90° (hottest summer temperature) on this basis:

0.09 per cent. boric preservative, and  
0.004 per cent. formaldehyde are the minimum amounts necessary in summer.

## Appendix.

## APPENDIX No. XXXII.

Handed in by Mr. *H. Droop Richmond*, as promised on January 22nd, 1900.

EXPERIMENTS on the use of hydrofluoric acid as a preservative of milk samples were published in "The Analyst" (1889-99). Hydrofluoric acid when added to fresh milk in the proportion of 0.5 per cent. was found to keep the samples in such condition that they gave the same results on analysis at times varying from a month to a year after the addition. If the milk had commenced to turn before the addition, the results were not so good. Carbon bisulphide, ether, dichlorophenol, chloroform and terpenes added to the same amount were unsatisfactory.

Further experiments in conjunction with L. K. Boseley ("Analyst" 1897-98) showed that chloroform was a better

preservative than boric acid, and thus it is indirectly shown that hydrofluoric acid is much better in its preservative action than boric acid.

A few experiments were made with Fluoboric Acid cream. About 0.02 to 0.03 per cent. was found to have an appreciable action as a preservative, and though accurate comparisons were not made, it was judged that fluoboric acid was at least five times more powerful in its action than boric acid.

Sodium fluosilicate was also experimented with, but was found to be too insoluble to be useful as a preservative.

## APPENDIX No. XXXIII.

Handed in by Mr. *J. M. Harris*, on Monday, January 22nd, 1900.

Laboratory, Plough Court,  
37, Lombard Street, London, E.C.,  
22 January 1900.

Dear Sir,

On the 21st November, 1899, I received from you two gammons of English bacon to be tested for boric acid. Later I received from you a gammon of Davies' Canadian Pea-Fed.

There was no difficulty in ascertaining the presence of boric acid in the fat and flesh near the surface. In order to ascertain to what extent it had penetrated a piece was in each case cut from about the middle, near the bone.

The following results were obtained:—

|                                            | First Gammon,<br>Harris's. | Second Gammon,<br>Oake, Woods &<br>Co. | Third Gammon,<br>Davies'<br>Pea-Fed Canadian. |
|--------------------------------------------|----------------------------|----------------------------------------|-----------------------------------------------|
| Boric Acid - -                             | 13 per cent.               | 10 per cent.                           | 12 per cent.                                  |
| Equivalent to<br>Borax per<br>lb. of meat. | 14.1 grains                | 10.5 grains                            | 12.6 grains                                   |

In each case borax could be readily detected on the outside.

A piece of fresh pork experimented upon in this laboratory showed boric acid in the interior of the flesh after the lapse of one week, to the extent of 10 per cent., equal to 10.5 grains of borax per pound of meat.

Yours faithfully,

R. H. HARLAND.

J. King Stewart, Esq.,  
The Bacon-Curers' Association of  
Great Britain and Ireland.

## APPENDIX No. XXXIV.

Handed in by Dr. *Philip Schidrowitz*, on May 8th, 1900.

## THE USE OF PRESERVATIVES IN BEER.

The great increase in competition in the brewing trade that has taken place in recent times, coupled with the huge sums which brewers are under present conditions practically compelled to expend on tied houses in order to maintain their positions in the trade, are, in my opinion indirectly the chief reasons which account for the almost universal use of preservatives in brewing which now obtains. Brewers have largely sought to meet the altered conditions by increasing their turnover—that is to say, by obtaining more beer from a plant of equal capacity than formerly, and this tendency has led to a very considerable reduction in the brewing time and also in the gravity of the beer brewed. It is by no means uncommon for a beer to be sent out of the brewery into consumption within a week or ten days from the time of mashing, and, working under these conditions, it is difficult to produce a good keeping beer without the use of preservatives. If such a beer were sent out "unpreserved," it would in the majority of cases deteriorate very rapidly, and it is hardly unfair, therefore, to say that one

of the chief objects of the use of preservatives in the brewing trade is to mask actual defects in brewing.<sup>1</sup> Without prejudice to the question as to whether the use of preservatives is or is not harmful, or should or should not be prohibited, I am of opinion that if the use of preservatives in beer was prohibited, brewers would, broadly speaking, be forced to brew a better article<sup>2</sup> and the consumer would be a distinct gainer thereby.

Whether injury to health is likely to arise from the preservatives used in brewing obviously depends on the quantity and frequency of the dose, but whether injurious or not, the use of preservatives must be considered to constitute a fraud where they are used to conceal the inferior character or manufacture of an article.

In view of the enormous consumption of beer in this country, amounting in 1899 to roughly thirty-one gallons per head of population, it is obvious that the use or abuse

<sup>1</sup> Beer Materials Committee—Grummit, 911; Wells, 1916.

<sup>2</sup> Beer Materials Committee—Stopes, 3373, 3250-3253.

of preservatives in beer is a question of considerable importance. Beer is not a food in the ordinary sense of the word, but it has considerable food value, and the consumption is so great that its albuminous and carbohydrate constituents form an appreciable percentage of the total proteid and carbohydrate food of the nation. By a simple calculation I arrive at the fact that roughly 2 to 3 per cent. of the total albumen and 5 per cent. of the total carbohydrate food of the adult population is taken in the shape of beer. A man drinking, say, four pints of beer a day, and consuming one and a quarter pounds of bread, and three-quarters of a pound of meat would (according to a calculation of Voit) take about 10 per cent. of the proteids and 20 per cent. of the carbohydrates in the beer alone.

The preservatives chiefly used in beer are—

1. The Sulphites (chiefly bisulphite of lime).
2. Salicylic acid.
3. More recently and in smaller measure Benzoic acid and the Fluorides.

I do not think that Formaldehyde is ever used in beer, and Boric acid very rarely, if at all.

With regard to *Salicylic acid* there can be little doubt in face of the evidence given before the Beer Materials Committee that it is used to a considerable extent. One witness<sup>1</sup> expressed it as his opinion that its use was abandoned ten years ago, but Mr. Bannister (late Deputy Principal of the Inland Revenue Laboratory) stated that it was used.<sup>2</sup> Sir J. H. Gilbert, examining Mr. Stopes<sup>3</sup>, said "With regard to the use of salicylic acid and bisulphite of lime, I think it is admitted that they are extremely largely used in Burton. . . ." Mr. Stopes<sup>4</sup> stated that salicylic acid is used by a number of brewers, and that he was told by a vendor of salicylic acid that he had 800 brewers on his books. Mr. Cassal<sup>5</sup> stated that he had prosecuted and obtained convictions for salicylic acid in beer. I was myself informed by the largest makers of salicylic acid in the world that their sales would fall off by a quarter if the use of this article were prohibited, and until quite recently there was a stall at the Brewers' Exhibition on which the wares of a well-known maker of the acid were prominently displayed. Some recent investigations carried out by the Connecticut Experiment Station showed that among a number of preservatives recommended for wine and beer one consisted entirely of salicylic acid, and another contained free salicylic acid 27.12 per cent. mixed with salicylate of soda and carbonate of soda.

It is stated that about one part of salicylic acid to ten thousand is sufficient to preserve beer, but there is reason

to believe<sup>6</sup> that under some conditions this would hardly be sufficient. On this basis, however, a man drinking four pints a day would consume about 0.3 grammes, or 5 grains of salicylic acid. The use of salicylic acid (as of all other preservatives) in beer is prohibited in Germany, but it may be put into beer intended for exportation. The use of salicylic acid is prohibited in France.

*Sulphites*.—The very general (for running beers almost universal) use of sulphurous acid, or rather its salts (principally the bisulphite of lime and the bisulphite of potash) is admitted on all hands. With regard to the quantity employed, Dr. Moritz<sup>7</sup> stated that the monosulphite is used in proportion to one ounce to the barrel (about one to five thousand), and the bisulphite a quarter to a half pint per barrel, but it is undoubtedly often used in much larger quantities.<sup>8</sup>

Sulphites are probably the least objectionable preservatives, but where used in excess or to mask deficiencies in the malting or brewing their use must obviously be condemned. They occasionally give rise to "stench" in beer owing to the reduction of the sulphite to sulphide by bacterial action. It is alleged that sulphites speedily become oxidised to sulphates, and, therefore, even if the former do exercise any prejudicial action on the human economy, it is a matter of little importance, as by the time the beer reaches the consumer the sulphite has become converted. This, however, is not the case with bottled beers, nor in cases where sulphites are used in anything like appreciable quantities in draught beer.

Artificial hop bitters are used to some extent in brewing. They are not used primarily as preservatives, but they certainly exercise a preservative action. They consist mostly of quassia and other natural bitters, and I think that their unrestricted and undeclared use is most undesirable. A substance which, I think, should be entirely prohibited is *Quillaia Bark*. (B.M.C. Minority Report—footnote. Hehner 7305. Mr. Bannister's list etc.)

Speaking broadly, I believe that the use of antiseptics in the manufacture of beer to be unnecessary when the same is produced on rational lines and from sound material<sup>9</sup>, and that the facilities for quick brewing afforded by their use are very often abused to mask inferior materials and bad brewing. I think that if the use of preservatives in beer were prohibited, or restricted, and declaration enforced, the consumer would be an appreciable gainer thereby.

## APPENDIX No. XXXV.

Handed in by Dr. Philip Schidrowitz on Tuesday, May 8th, 1900.

I.—The mixed (evening) milk of eight healthy cows (two Jerseys and six Shorthorns) on a diet of mangels, hay, barley meal, and equal parts of cotton and linseed cake, was strained and then rapidly cooled to 10·5°C. The milk was then brought up to London by myself in the water-jacketed tin alluded to above. Maximum temperature attained by milk prior to starting experiments 10·5°C. Experiments started 19 hours after milking. Initial acidity of milk 14·7 degrees.

a = time after incubation. b = time after milking (hours.)

II.—Mixed (morning) milk of same eight cows as in I. Milking vessels scalded immediately prior to milking. Cooled to 10·5°C as before. Maximum temperature of milk prior to experiments 11°C. Experiments started 10½ hours after milking. Initial acidity 14·7 degrees.

a = time after incubation. b = time after milking.

| 40½                      | 51  | —        | Curdled, but no unpleasant odour.     | 41·3                     | Coagulates: slight odour.              | 18·9                     | Smells badly, but does not coagulate. | —                     | Curdled, smelt                     | 67·1                  | Not curdled but smells badly. |
| 47½                      | 58  | —        | —                                     | —                        | —                                      | 34·4                     | Almost curdled, smell disappeared.    | —                     | —                                  | —                     | —                             |

NOTE.—The odour (and smell) referred to in above table was of a peculiar bitter nature, and not at all like the ordinary odour of "turned" milk.

III.—Mixed (morning) milk of same cows as in I and II. Milk not cooled in any way. Otherwise as in I and II. Maximum temperature prior to experiments 29.5°C. Minimum do. 22.0°C. Experiments started 10 hours after milking. Initial acidity 16.1 degrees.

a = time after incubation. b = do. after milking.

## APPENDIX No. XXXVI.

## MEMORANDUM on the Use of Preservatives in Dairy Produce, by Mr. John Boyd Kinnear.

In any enquiry whether so-called preservatives are injurious to health there is the previous question whether they are at all necessary. From a tolerably large practical experience in the matter of dairy products, I am able to answer that question in the negative.

For some dozen years I have kept on some farms in my own hands a herd of about 120 cows of pure Guernsey breed. Their milk is chiefly sold in two shops belonging to me, one in St. Andrews, 20 miles distant by rail, the other in Edinburgh 40 miles distant. What is not sold as new milk, cream, or skim, is churned, and the butter is sold as fresh at the same shops. I am therefore brought into direct contact with every consumer, and I hear with great promptitude of any defect occurring in any article.

As the milk is of specially high quality, and is sold at a price above the usual rate in both towns, the customers are even more than usually particular in reminding me, quite justly, that for a high price they are entitled to perfect milk.

But this standard I have been able to attain (subject to extremely rare exceptions, always traceable to some accidental negligence) without the use of any preservatives either in summer or winter. This success is due to observance of the condition of scrupulous cleanliness in the cows, in their surroundings, in the milkers, and in the milk vessels. Further the milk is generally refrigerated in the usual well-known method. But I have found by an experience of three summers, that the main virtue of refrigeration is not the cooling, but the exposure to the atmosphere in a thin stream when freshly drawn from the cow. A wire gauze is supplied for this purpose by Gray of Stranraer, and I find that milk poured over this gauze and sent off only slightly cooled keeps as well as that which has been fully cooled. It is equally well de-

prived of the animal odour, and it would seem that this effects the removal of the primary element of decomposition.

The points in which special cleanliness is observed are briefly these. The byres or sheds are open to the roof and thoroughly ventilated, while most of them are lighted by skylights, which give a much stronger light than side windows. The floors are of concrete, and passages and gutters are daily washed till the water runs perfectly clear. The droppings are drawn back from the cows frequently, so that at least during the day they do not soil themselves, and twice a day the dung is carried out in wheelbarrows, while the urine flows at once into an outside tank. Every morning the first work is to wash such of the cows as have dirtied themselves in the night, and, besides this, every milker washes the teats of each cow in a basin of clean water before each milking. The milkers themselves are provided with clean white aprons. Thus no dust or impurity either from the cows, the litter, or the milker's dress can enter the pails. The cows themselves are brushed daily during the forenoon. The atmosphere of the byres is at all times as sweet as that of a drawing-room.

The usual precautions of washing and scalding all utensils are of course observed. It may be observed that, any occasional case of premature acidity in the milk can always be traced to some neglect in the purification of the cans, such as using water for scalding that is not quite boiling.

Under these conditions milk may be depended on to keep sweet for 24 hours, even in the height of summer and subject to the disadvantage of a slow railway journey. In exceptionally hot weather the cans are covered with a wet woollen jacket when despatched. Ice is not employed; but this article, now so cheap, would afford an

## Appendix.

additional means of preservation, if requisite. It is a fact that weather in Scotland is never so hot as it is in certain summers in England, but ice would be more than sufficient to meet this difference, and if the trade were to combine they could oblige the railway companies to provide cool vans, as for meat.

It may therefore be stated with confidence that no antiseptics are necessary for conducting dairy operations, provided perfect cleanliness is enforced.

Apart from the question whether the use of antiseptics is injurious to health, there is the distinct objection to them that they mask uncleanness. Filth from the cows, from their litter, from the dress of the milkers, may all pass into the milk and be swallowed with it undetected, if antiseptics are used to prevent the natural action of such filth in setting up decomposition. In the interest of purity alone they ought therefore to be interdicted.

It must, however, be conceded that the conditions of cleanliness do involve a certain expense, and therefore may involve a rise of price. This holds true of all articles and not of milk and butter only. And as there is a certain number of people who prefer cheapness to purity, it may be proper to permit the continuance, at their own risk, of the use of antiseptics in articles of food. But at least they ought to be informed, so that they may make

their choice. All articles which are thus preserved ought therefore to be distinctly labelled "Preserved," and the packet or vessel in which they are handed to a purchaser ought to have such a label affixed to it. Exception may be made of such preservatives as declare themselves by their taste or smell, and which are at present recognised as harmless, such as salt, sugar, vinegar, alcohol, wood smoke, or substances derived from distillation of wood. But all other antiseptics should be allowed only if expressly notified to the purchaser.

The same rule should be applied to colouring materials. They are used for the purpose of representing an article to be what it is not. If any purchaser likes his food thus dyed by all means let him have it. But at least everyone should have his choice. The word "Coloured" should be required to be affixed to all articles of food thus artificially stained when offered for sale. No one can object to such a rule except in the interest of fraud. The plain rule of honesty is that every customer should know exactly what he is buying; if the trader tries by antiseptics or colouring to represent an article as fresh when it is not, or as having a natural colour when it is artificial, the law should certainly declare the attempt to be an offence.

---

## PRECIS OF EVIDENCE.

ANDERSON, MR. ALEXR. RICHARD. (Digest of his Evidence.)

F.R.C.S., 7184, and Surgeon to Nottingham General Hospital, 7185.

Boracic acid prescribed by witness, 7186, 7210, and its effects observed, 7187. From 30 to 60 grains daily for bladder disease have frequently caused dyspeptic disturbances sufficient to cause misery, the symptoms quickly subsiding on the acid being given up, 7188. The acid is an irritant, and therefore bad in typhoid fever, 7190. It is a very feeble antiseptic, 7191. No evidence of skin eruptions from antiseptic use of the acid, 7192. No practical experience of harm from boracised food, 7203. Serious dyspeptic trouble likely to accrue to child taking 10 grains a day in milk, 7204. Should not be used indiscriminately in milk, 7207. Boracic acid treatment of infantile diarrhoea would be bad, 7213-15.

Contra-indication of boracic acid in fevers, 7205-6, and in all disorders entailing milk diet, 7208. Would not give the acid in nephritis, 7209.

Salicylic acid, as salicylate of soda, produces distinctly unpleasant symptoms, 7211-12.

Prohibition of boracic acid in milk urged on account of harmfulness to children and also adults in ill-health, 7189.

Medical men should know if patients are taking drugs in their food, 7197, 7204. Their position might be stultified, 7198. Harm caused by milk in one instance, 7198-7202.

Milk of Nottingham General Hospital tested for preservatives, 7193-96.

ANNETT, DR. HENRY EDWARD. (Digest of his Evidence.)

Doctor of Medicine, Diplomate in Public Health, Demonstrator in Tropical Medicine and Pathology, 2634-35.

Experiments made as to formalin and boracic acid in milk, 2636, and these preservatives found, 2637-39. Formaldehyde in milk,  $\frac{1}{50000}$ , retards the growth of kittens, 2640-41. In  $\frac{1}{25000}$  still greater retardation of growth results, and still greater in  $\frac{1}{12500}$ , 2641. Boracised kittens with 80 grains of boracic acid to a gallon of milk, and 40 grains also, became emaciated and died, 2647. They had diarrhoea, 2648. Balance of unassimilated nutriment probably voided, 2649. Control kittens used, 2650. Amount of boracic acid taken by kittens not known; all had unstinted milk supply, 2653, 2655, 2690. Matter unimportant, 2654. Ten boracised kittens took about a quart of milk per diem, 2656-59. Kittens hardly susceptible to boracic acid after three months old, 2660, 2662, 2671-72, 2694, 2704. Susceptibility decreases gradually, 2695. Reason unknown, 2698-2701. *Vice versa* experiments on kittens not attempted, 2660-61. Relative immunity of infants not known, 2696. Drs. Rideal and Foulerton used older kittens, hence results differed, 2663, 2691-93. Chittenden's experiments were made on full-grown dogs, and also and for that reason differed, 2664. Experiments of witness lend argument to effect of boracic acid on infants only, 2666. Investigation on young animals to be preferred to adult animals and to experiments *in vitro*, 2673-74. No experiments made on kittens fed normally up to three months, 2703. Dr. Foulerton obtained no result with kittens of that age drinking boracised milk, 2705.

Animals insusceptible to anthrax not known, 2669. Susceptibilities of mice to anthrax known, 2670.

Formaldehyde as a preservative in milk not always effective for 48 hours in  $\frac{1}{50000}$ , nor for 24 hours in  $\frac{1}{25000}$ ; but  $\frac{1}{12500}$  does preserve it for 48 hours, 2642. About one-third of tumbler used in experiments, 2643-44.

Injurious effects of preservatives in milk, formalin and boracic acid, in proportions used in kitten experiments, held to be decided as regards infants, 2651-52. As regards adults, effects probably idiosyncratic, 2666. Thirty grains per diem known to have produced severe symptoms, 2667. Kittens, like infants, dependent on milk diet, 2668.

Digestive disturbances of preservatives not clearly defined. No doubt there is considerable inhibitory action on enzymes, 2697.

Diarrhoea mortality in infants probably related to preservative milk, 2675-80.

Prohibition of preservatives in milk needed; they admit of its manipulation and of general uncleanness, 2685, and would tax infants' digestive powers, 2689.

Milk, keeping power in large quantities not known, 2645-46. Boracic acid, in proportion of 35 grains per gallon, believed to be deemed requisite to keep milk for 48 hours, 2647. Milk should be preservative soon after drawn, 2681. Acidity as a full indication of decomposition of milk not known, 2683-84. Sour milk injurious to infants, 2685. Veiling of decomposition by added boracic acid not known, 2686, but not likely, 2687-88.

ATTFIELD, PROF. JOHN. (Digest of his Evidence.)

Doctor of Philosophy, F.R.S., Professor of Practical Chemistry, Editor of the British Pharmacopoeia, &c., 6491-94, 6532.

Physiological action of modern preservatives studied, 6495, as used by witness for personal dyspepsia under medical advice, 6496. Boracic acid taken, from 10 to 15 grains thrice daily, as sufficing to prevent abnormal stomachic decomposition of food, 6497, but larger doses have been taken, though 10 grains found sufficient, 6497-98. As much as 70 grains daily taken experimentally, 6499. No inconvenience resulted, 6500. Boracic acid voided through the kidneys, 6501, how much daily not known. The acid peppered on fibrous food at meal-times, 6502, 6513-15. No bad effects on digestibility of food noticed, 6503-4, rather the reverse, 6503-6, 6512. Action of certain bacteria inhibited, 6507-9. Stomach washed out and contents examined, 6502, 6510-11. Nothing much to be learned from bacteriological examination of the contents, 6516-19. Retardation of digestion of salted and smoked foods not due to antiseptics, 6520. Formalin never taken, 6521. Sodium hyposulphite taken, from 15 to 45 grains per diem, prevented discomfort attending fibrous foods, but at times unpleasantness resulted, 6539-44, but experience not of same value as that with boracic acid, 6545. Inhibitory action of preservatives on bacteria of decomposition, and therefore also on digestion, not true in witness's judgment, 6546. Conceivable that infants may suffer from preservative milk; no evidence of such suffering in witness's possession; and Dr. Bell gives evidence to the contrary, 6552-54. A question of quantity arises, 6555-56. Desirable to know the quantity of boracic acid being taken with food, 6557, but matter not of great importance, 6558-59.

Salt scarcely more a food than boracic acid, 6549, but it is a component of the human body, 6550. Salt betrays its presence in food, 6551.

Salicylic acid may be taken from 5 to 15 grains at a time without retarding digestion, 6568.

Formalin has an extremely hardening effect on gelatin in strong proportions, 6521-30, 6566, of 40 per cent. solution, 6531. As a constituent of food action not known, 6567.

Boracic acid dose reduced in Pharmacopoeia because present dosage produces all needed effects, 6533-35, and larger doses do no more, 6536. Has taken 100 grains in one day, 6537, and has kept up

Précis.

Précis.

45 grains daily for weeks, 6538. Boracic acid found in many vegetables, in wines, and hop plant, 6550. Boracic acid has no flavour, 6551. Eighty grains to the pint of milk a very large dose, 6560-61, but probably an isolated case, 6562.

Declaration of preservatives not objected to, if and so far as practicable, 6547.

Prohibition of indiscriminate use of boracic acid should be enforced if large doses are put into milk, 6562-65, and objection lies to the indiscriminate use of formalin, 6567.

Idiosyncrasy a matter of importance *quâd* preservatives, 6569.

Colouring matters of a harmful character not come across, 6570-71. Common knowledge that some harmful substances are used, 6572. Copper found only in very minute amounts in vegetables and jams as regards a particular firm, and inference drawn of accidental admixture by method of manufacture, 6573.

BANNISTER, MR. RICHARD. (Digest of his Evidence.)  
Late Deputy Principal of the Inland Revenue Branch of the Government Laboratory, and a Fellow of the Institute of Chemistry and Chemical Society, 3482-83.

Bacon preserved with borax after cure with salt and saltpetre, 3484, and ham also in England, 3648. Bacon can thus be mild cured, 3485, and is not imported in other ways, 3486. Packing in borax is inexpensive, 3488. Refrigeration would be more expensive, 3489-94. Bacon packed in borax not known to have been harmful, 3494. Borax a necessity to the bacon trade, 3495-96, 3498-3500, owing to change of public taste. Rancid bacon no longer saleable, 3497. Bacon brought in as is fresh meat would not be in same condition as borax-packed bacon, 3501. Necessary for mild-cured bacon and ham to have from 4 ozs. to 1 lb. of boracic acid per 112 lbs. of meat, 3649-51, in powdered form, 3652-53.

Meat is imported fresh in refrigerators, 3487. If kept it is dusted with borax, 3626.

Refrigeration involves expense, 3488.

Butter trade to-day demands a preservative, 3502-3, 3532, as regards factory and creamery butter, 3536-37. Creamery butter without preservatives goes off quickly, 3538, and many factories use them, 3539. If for quick consumption preservatives not a necessity, but necessary if the butter required to keep, 3540. Necessity not universal, 3541, even in creamery butter, 3542-43. Danish butter contains only salt, but cannot compete with Normandy fresh, 3504. Latter fetches a higher price, 3505. About 2 per cent. of salt in Danish butter, 3506, but amount varies, 3507-8. Finest quality under 2 per cent., 3509-12, but very best class not over 1 per cent., 3513. Danish is tub butter, Normandy is factory butter, 3513-14. Danish butter compares with the old Irish butter, 3515, which was salty, 3516, and tub butter, 3517-18. Danish butter a substitute therefor, 3519-20. Some Irish butter equal or superior to Danish, 3521. Some old Irish butter was not heavily salted, 3522, 3530-31, made in summer, 3523, without abnormal quantity of water, 3524-26, with exception, 3527-29. Irish butter lost the market by being only a seasonal trade, 3533, Denmark stepping in with an all-year-round trade, 3534, and with its unpreserved butter driving Ireland out, 3535. Normandy butter contains either salt or preservative, 3544-45. Butter refrigerated decomposes readily on defrosting, 3626-27.

Milk sour probably more harmful than boracised milk, 3546. Prevalence of preservatising of London milk not known, 3547; nor proportion in milk, 3548. Diffusion of preservatives in milk may be partial, 3631-32; but this no argument against their indiscriminate use, 3633; but there might be danger of over-dose of boracic acid in some portion of the milk, 3634. Simple declaration would not cover this risk, 3635. Sixty grains of boracic acid have been found in a gallon of milk, 3636. Eighty grains per pint would taste the milk, 3637-38, 3640. Such a quantity should be declared, 3639; it counter-balances any trade requirement, 3640. Boracic acid a seasonal necessity in milk trade, 3641. Great difficulty in carrying on milk trade of a large town in summer else, 3642-44. A small number of samples examined does not represent Birmingham milk, 3645-46. If only 9 per cent. of milk there is preservatised no great commercial necessity for milk

preservative, 3647. Decomposed and sour milk a danger *quâd* disease and infantile mortality, 3654, diarrhoea and wasting, 3655. Some of the diarrhoea doubtless due to preservatives, 3656-57. Boracic acid prejudicial to children's health, 3658. Milk should not be formalised, 3660.

Copper in peas, as used in France, need not be prohibited. Coppered peas command a large sale, 3560. It preserves their natural colour, 3561-68, but old peas are not used, 3569. It recolours peas that are off colour, 3570. No fraud in question, 3571-72. Public demand the colouring, 3573-74. Consumer not prejudiced by the practice, 3575-80. Copper albuminate not dissolved during digestion, 3581-85. Reason not known, 3586. No harm known from consumption of coppered peas, 3587-89, 3608-11. Copper is a poison in large quantities, 3590, but not known to be cumulative, 3591. Declaration of presence of copper would seldom meet consumer's eye, 3592. Such peas mostly used in large establishments, 3593. Too much copper cannot be put in without spoiling the peas, 3597, and ~~10000~~ is the most found; ~~7700~~ being regarded as a fair average by French Government, who have not interdicted the practice, 3598. Mode of diffusion of copper in peas not known, 3599, but thought of as general, 3600. Some think copper is associated with the chlorophyll of the pea, 3601, outside the pea, 3602-4, tending to its concentration, 3605. Physiological action of eating coppered peas not known, 3606-7. About ~~10000~~, or 2.9 grains of commercial copper sulphate per lb. of peas would be a safe amount, 3612. Copper sulphate used as an astringent in doses under a grain, 3613. But action in peas is not known, 3614-18. Ten grains per lb. of copper sulphate never found, 3619, because copper not there as a sulphate, 3620-25.

Beer preservatised most often by sulphurous acid, 3661, 3668-70, in small quantity. Also used for cleaning brewery vessels, 3662. Salicylic acid not used in this country, 3663-64. One case of lager beer being salicylised, 3666, 3671. Bottled beer needs no preservative, 3666-67.

Cider may be salicylised, it requires a preservative, 3665.

Salicylic acid used in wines, liquids of weak alcoholic strength desired to be clear, and imported fruit pulps, 3558. Proceedings taken for its use in lager beer and orange wine, 3559.

Formalin is dangerous, 3659, acts directly on milk curd, is a poison, and an antiseptic, 3660.

Sulphurous acid not to be classed as an antiseptic with formalin, 3672; it keeps changing into a sulphate, a natural constituent of beer, 3673, and is not dangerous, 3674.

Colouring matters might be declared, 3678.

Declaration as to preservative in milk not objected to, 3549. Difficulty in stating amount, 3550, because of insolubility of boracic acid and difficulty of exactly estimating its presence, 3551-53, 3628, and uniform diffusion, 3629, even in milk, 3630, and liable to repeated dosage, 3558. Qualitative analysis easy, 3554. Declaration would tend to limit amount used, 3556. No objection to declaration of copper in peas, 3592, 3594, 3596. Fact is stated in Pennsylvania, 3595. No objection to amount of copper being stated, 3597. Declaration of preservatives generally not objected to, 3677.

Prohibition of preservatives would seriously interfere with trade, especially dairy trade, and provision trade generally, 3675-76.

BELL, DR. ROBERT. (Digest of his evidence.)

Doctor of Medicine, Member of the Royal College of Surgeons, Edinburgh, Fellow of the Faculty of Physicians and Surgeons, Glasgow, 2781-82.

Borax and boracic acid studied as used in medicine and surgery, 2783-84, and these only, 2795. Boracic acid a saturated solution of 1 in 30, 2827-28.

Physiological effects of boracic acid used medicinally in moderate doses beneficial, 2786. Extreme case of saving of life by its use, 30 grains daily, 2787, 2789. Borax constantly sucked for years without ill effect. Boracised milk long taken without ill effect, 2787. No ill effects would follow consumption of boracic compounds by the community unknowingly, 2788. Forty grains per diem not dangerous, 2790, nor 50 grains, 2811, nor 90 grains daily, 2791, 2824-25. In a surgical case several lbs. used on a raw surface

without ill effect, 2793. There would be great absorption into the system, 2794. In his experience no ill effects have followed absorption, 2796. Boracic acid largely used by most eminent surgeons, especially for washing out the bladder, 2797. Fatal results following internal washing with the acid would equally have followed the use of water, 2799. Own experience preferred to that recorded by others, 2800-2. Boracic acid has no cumulative effect, 2826. No ill effects from its use known, 2834, but opinions differ, 2835, and prejudice is at the bottom of adverse opinion, 2836.

Dose reduced by "Pharmacopœia," reason not known, 2803, nor fact; doses therein not followed because empirical, 2804. Ten grains suffice to produce a medicinal effect, 2805-6, that is 30 grains a day, 2807. Boracic acid may be administered in all conditions, 2808, in nephritis, 2809-10. Fifty grains an absurd and unnecessary dose, 2813, to adults, 2815. Would not give a child 40 grains, 2816. That amount in milk would show meddling with the food, 2818.

Declaration of boracic acid in food not necessary, 2793, nor approved of, 2831, but objected to, 2832-33.

Prohibition of boracic acid not necessary, 2812, not even if 26 grains were added to a pint of milk, 2817. More good than harm done by the use of the acid, 2814.

Salt and saltpetre bulk for bulk more harmful than boracic acid, 2791, but these would be detectable in food, 2792. Saltpetre would spoil milk, 2819.

Milk of Glasgow Dairy Company boracised, 2787. Milk so treated better than putrid milk, and has no toxic effect, 2826. A saturated solution can be easily distributed uniformly, 2827-28. Milk difficult of manipulation without boracic acid, 2839, even when pasteurised, 2840, because germs of decomposition are arrested only, 2841; but germs of disease are killed thereby, 2842, and this a positive gain, 2843, and there is a gain in time, 2844. But decomposition takes place quickly in hot weather, 2845. Copenhagen method of milk distribution unknown, 2846. Milk should be sterilised, 2847, but a little boracic acid also put in, 2848.

Cream in jars if preservatised in its top parts, not properly treated, 2829. Preservatives not needed in cream, 2830, 2837, 2839. Cream a substance liable to change, 2838.

Bacon mild cured by 0.6 per cent. of boracic acid better for stomach than old salt cured bacon, 2821. Cure suggested by injection of boracic acid; bacon probably steeped in the acid, 2822. Details of cure not known, 2823.

Hams cured by 0.6 per cent. of boracic acid, 2823.

**BENNETT, MR. J. WHEELER.** (Digest of his evidence.)

Appears on behalf of the London Chamber of Commerce, 126; and represents largest curing house in British Empire, 130.

Canadian products sprinkled with about 4 ozs. of dry borax to 56 lbs. during last 20 years, after curing has been effected; product immersed in water, and borax washed off on arrival in this country; then drained and smoked, 128-30, 184-87; witness has eaten bacon thus treated for 20 years, 138; 80 per cent. of borax always lost in washing process, and all of it in winter, 140-42; no method other than by sprinkling known, 151.

Increase of Canadian bacon and ham trade enormous in last 10 years, 130; and excessive in 1892 over preceding year, by reason of notoriety, and of demand of English market, and of better prices, 233-36.

Home bacon trade small, because unpopular, 131-32; firmer and harsher in cure than Canadian products, 137; relation to imported produce very small, 161-62.

Borax not noticed in English and Irish as in Canadian bacon, 135; dry borax only used on Canadian products, 138, 143-44; use became general 20 years ago, 232; does not penetrate the meat, 140, 148, but might, if contact in boxes lengthy, and large amount used, 152-55; if used in appreciable amount it would taste the meat, 148-49; amount used in butter infinitesimal, 150.

Bacon non-absorbent in winter, 142.

Saltiness of bacon to excess held in check by use of borax at proper stage of cure, 145-47; salted goods not now appreciated or eatable, 176-78.

Prohibition of borax would ruin the Canadian American, and Australian trade, as to hog products and butter 156-60 166-68; prices of hog products 3017.

would go up largely, 163, 165; people would thus be deprived of these products; even Continental produce would be checked except for immediate use, 166-70; and salted meat or none at all would be the result, 175; competition by other countries would cease, 178.

Other methods of preserving produce than by borax unknown, though sought, 171; no other desired, 172.

American bacon and hams first imported some 50 years back, in a crude condition, 173; imports have increased by leaps and bounds in last 20 years, by reason of perfection of quality, 173-74.

Curing process described, 182-84.

Tainted bacon caused much loss before preservatives used, 188, even though more salt was then used, 189-90; no tainted bacon now, save by negligence, 188; former market, at a large loss, for tainted bacon, no longer exists, such meat would now be seized, 191.

Injections of borax in solution into carcase not known; meat would imbibe the taste, 192.

Butter from Australia and France washed with a solution of borax, and trade largely increased, 194-98; no rancid butter now as a result; French butter comes in wrappers soaked in a solution of borax; previously it went rank in 48, and even in 24 hours, 199; method very effective, even for Colonial butter, 202-3; exporters advised as to this method, 208, 214; butter thus dealt with not penetrated by the preservative, 204-5; borax not mixed with the butter, 200-1; no mixture of butter and preservative in France, 209; and not known to obtain in Ireland, 219-20; no stipulated conditions as to French butter, 210; heavily boraxed butter would not be rejected by witness, but its taste would lead customer to reject it, 211-13; by reason of its aroma, 216-17, 228-31; but a lot of borax would be needed to this end, 218; such a butter never seen, 215; not aware of cases of excessive weights of borax in butter leading to proceedings, 221-26.

Lard, well made, requires and receives no preservative, and will keep long, 206.

**BLACKWELL, MR. THOS. FRANCIS.** (Digest of his Evidence.)

Chairman of firm of Messrs. Crosse and Blackwell, 4857.\*

Preservatives not known to be used in preserved fruits and jams; not used by Crosse and Blackwell, 4863-64, 4871 4875, and quite unnecessary, 4865, 4872, 4918-19. None used in jam pulp, 4866-67, nor by the firm in potted meats or fish, 4868-70, nor in lemon squash nor lime-juice, 4884-85. They would be convenient in the latter, to prevent moulding, 4886, and are no doubt largely used, 4887-88.

Jam from imported pulp only as regards apricot made by Crosse and Blackwell, 4905-7, and believed to be free from preservative, 4908-9, which would flavour the pulp, 4910-13. No preservative needed in any pulp, 4914-17. Preservatives do not cheapen jam, 4920-22.

Colouring of jams by cochineal extract only colouring known, 4879, in small quantity and harmless, giving uniformity of colour, 4880-83. Pickles not coloured for many years, 4885. Red earth used for essence of anchovies, 4889. Public demand a pleasing-looking article, without question of process adopted, 4891, being quite indifferent thereto, 4891-95.

Copper supposed to be used in foreign preserved peas, beans, and vegetables. Crosse and Blackwell have sold uncoloured peas; not large trade, 4876; no demand here, but large export trade, 4877. Method of adding copper to peas not known, 4896. French peas coppered abroad, 4901.

Declaration of colourings should be made: Crosse and Blackwell declare them in some cases, 4878 4898; and also of nature, 4899, and amount, 4900.

Declaration of preservatives should be made, 4874, 4897; and nature, 4899, and amount, 4900.

Prohibition of preservatives not deemed essential if moderate quantities only used, 4873.

Analyses made for Crosse and Blackwell by a professional adviser, 4902-4.

**BLAXALL, DR. FRANK R.** (Digest of his Evidence.)

Doctor of Medicine, Lecturer in Bacteriology, Bacteriologist to the Vaccine Department of Local Government Board, 6042-43.

Experimental work done as to preservatives in food

Précis.

Précis.

6044, as to sterilisation of milk by formalin, 6045. Age of milks used in experiments not known, but deemed of recent milking, 6066, but element of uncertainty in results, herefrom, 6085. Experiments made on scientific basis, not from a commercial standpoint, 6071-73. Commercial usage of preservatives not known, 6074-76. Experiments made from May up to and during winter, 6115. All milks tested for formalin, but not all for boracic acid or salicylic acid, 6053, 6116-18, and no reason to suspect their presence, 6118-25. Bacilli in experimental milk not differentiated, 6126.

Formalin in  $\frac{1}{500}$  kills all germs in milk, which latter can be kept indefinitely, 6046-51. Method of procedure adopted, 6052-54. Thirty-eight experiments made, 6059. Control unpreserved milks nearly all went sour in 24 hours, in hermetically sealed flasks, 6055. Sour milk preserved had as many organisms as the control milk, but sweet milk not so, 6056. Bacteriological fermentation not seasonally different under the conditions of the experiments, 6057-58. Formalin  $\frac{1}{1000}$  will keep milk sweet for a short time, 6078, possibly 24 hours at 60° F., 6079, not at 80° F., 6080-82, the 24 hours being it may be from 36 to 50 hours after milking, 6083-84. In  $\frac{1}{5000}$  formalin no use for keeping milk 24 hours in summer weather, 6086-91, 6095, 6098, and would not prevent formation of lactic acid, 6099-6101, but  $\frac{1}{500}$  would keep it for 24 hours at 70° F., 6107. Specification of formaldehyde on the constituents of milk not known, 6092-93. Formalin of experiment guaranteed as a 40 per cent. solution but not tested, 6112-14. About  $\frac{1}{7000}$  would kill typhoid bacilli, 6142, and  $\frac{1}{500}$  any bacteriological organisms in milk, 6146, and render milk unsaleable, 6151. Formalin hardens sections, 6143-44. Organisms in milk diminish rapidly on addition of formalin, 6147-48. Volatile nature of formalin not known, 6149-50.

Boracic acid less powerful as a germicide and antiseptic than formalin, 6061, 6094, and also as a preservative, 6067-69. Boracic acid up to  $\frac{1}{3}$  will not sterilise milk, 6062; fermentation ceases, but organisms grow freely, 6064, 6129. Milk will only take up about  $\frac{1}{25}$ , 6063. In  $\frac{1}{200}$  milk sours in 24 hours at 80 deg. Fahr., 6064-65. In  $\frac{1}{2000}$  no effect in keeping milk sweet during summer weather, 6096-98, and would not prevent formation of lactic acid, 6099-6101; but  $\frac{1}{200}$ , an undesirable amount, would keep milk sweet for 24 hours at 70 deg. Fahr., 6108. About  $\frac{1}{100}$  or 5 grammes per pint will produce inhibitive action in milk, 6127-29. - A proportion altogether in excess of the pharmacopoeial dose requisite to keep milk sweet, 6130. Inhibitive action of boracic acid apart from milk not experimented on, 6131-32.

Salicylic acid as ineffective as boracic acid as to milk sterilisation; milk practically saturated,  $\frac{1}{100}$ , not sterilised, 6070.

Sourness of milk the essential test of its injuriousness, 6102-6, but a poor test of other changes going on in milk, 6137; but smell distinguishes nearly all harmful lactic changes, 6138-39.

Preservatives' antiseptic power in relation to toxic equivalents not known, 6109-10, but important, 6111. Preservatives have a selective action on organisms in milk, 6133-36.

Germicidal power of preservatives different on different bacilli, 2140-42.

BLYTH, PROFESSOR A. WYNTER. (Digest of his Evidence.)

Public Analyst, &c., 3348-50.

Colouring of foods with aniline dyes rare years ago; but for last eight or ten years sweetmeats and other articles coloured with coal tar colours, 3351, and these latter doubtless cheaper by reason of greater tinctorial power, 3352, and found in sweetmeats, jams, jellies, and one sample of Burgundy wine and suspected in butter, 3353, 3366. Grape juice sufficiently colours wine, 3354. Aniline colouring not found in dangerous proportion in any one article, but the accumulated effect of eating many articles so coloured might injure a child, 3358. Colourings in dairy produce not separated by witness, 3365-66.

Vegetables of bright green found to contain aniline dye, 3356. Copper found in many and in all of French origin. It is a natural constituent of vegetables, 3357, 3376. Fact disputed by a French chemist, 3387-91.

Copper found in peas, flour, bread, tobacco, and ash of lime tree, 3377. Method of detection, 3378-86, at fault, 3387-91; but copper held to be natural to peas, 3391; but fact not known apart from general acceptance and witness's own experiments, 3392-95. A certain amount of copper in peas would not be injurious, 3421; amount not remembered, 3422. Some 4 to 5 grains per lb. have been found in peas, 3423-25. No physiological result anticipated from 5 grains per lb. of peas, 3426-27, 3429, 3433. Solubility in gastric juice or human economy doubted, 3428. Pharmacopoeial dose of sulphate of copper from  $\frac{1}{4}$  to 10 grains, 3430-31. Some limitations should be fixed, 3432-33. Wrong to use a strong poison to simply colour food, 3434.

Sweetmeats of red colour nearly always coloured with rhodamine or analogous colour, 3369, not a noxious substance, 3370.

Macaroni coloured by Martius' yellow, 3358, 3362, in very small quantity, 3363. Its presence can be detected by analysis, 3364.

Wines not coloured on any scale, 3355. One sample of Burgundy found to contain colouring like fuchsine, 3413-14, quantity unknown, 3415. Liqueurs not examined, 3416.

Beers found only to be naturally coloured, 3419.

Declaration of nature and amount of colouring matter should be stated, 3435. Difficulty in determining the exact quantity of copper, 3436-37.

Prohibition of certain colours advised by Weyl in Germany, 3358. Certain colours, including picric acid, believed to be prohibited in that country, 3359. Injurious colours should be scheduled, 3360, for all produce, 3361. Not a matter of difficulty *quid* analyses, 3371-75.

Dangerous colours held by Weyl to be picric acid, dinitrokresol, Martius' yellow, Bismarck brown, orange II., and metanil brown, 3358. Case of poisoning by dinitrokresol, 3360, recorded by Weyl, 3396-97. Harmfulness of dyes could probably be determined by long continued experiments on animals, 3398, by multiple experimenters, 3412. Colours scheduled in Belgium, 3399-3400. Fuchsine classed as poisonous, 3401, by an error of opinion, 3402-3. Some such arrangement as obtains in Belgium and Austro-Hungary would meet the case here, 3404, without difficulty, 3405. Classifications should be elastic, 3406. Power of alteration should be vested in Local Government Board or Board of Agriculture, 3407, or in a Standing Committee, 3408, both as to colourings and preservatives, 3409. Standing Committee generally agreed upon as being useful, 3410. Classification would have to be made on general principles, 3411. Salts of copper, picric acid, and impure aniline dyes occasionally used, 3417, but not within personal experience, 3418. Dinitrokresol would presumably derange a child's digestive organs even in small quantity, 3420.

Analyses often rendered difficult as to quantities by smallness of samples, 3364, 3369. Almost any aniline dye can be detected, 3367; the amount of dye being relatively very small, 3368.

Preservatives in common use are boracic acid, borax, salicylic acid, and formaldehyde, 3439; the latter a stronger antiseptic than the first, 3463.

Salicylic acid found in temperance drinks, to arrest fermentation, 3460.

Borax given for thrush, up to 20 grains a day without seeming harm, 3464-66. A child taking 160 grains a day, as is possible in milk, would be injuriously affected, 3467. Quantity to be used should be restricted, 3468. Cumulative effects disproved by Liebrich, 3469. Other recorders point to accumulation, 3470. Continued dosage tends to harm, 3471. Witness idiosyncratic to boracised cream, 3472. Medical men should know if their patients are taking boracised food, 3473.

Declaration of preservatives should be made, 3458; and would serve as a safeguard against their repeated use, 3459. Preferable to labelling, 3474-75.

Milk often dosed with boracic compounds in summer; seldom in winter; but one sample found in December to contain 80 grains of borax per pint, 3439, 3442. But skim and fresh milks may have been in question, 3444, both boracised, 3445-46. Case rare, but found at times in summer, 3440. When added not known, 3441. Boracised milk often watered, 3442, probably owing to mode of admixture of preservatives, 3443. Preservatising of milk not approved of, but London trade demands it, 3447, as now organised, 3448, 3476-77, as does that of other large towns, 3478-79. The matter one of rapid

transit, 3480-81. Boracising of milk many years in vogue, 3454, but not found in country milk twenty years ago, 3455. Much London milk not treated now, 3456, but retail dealers in poorer parts create a difficulty, 3457. Milk should be available free from preservatives, 3458.

Pasteurisation possibly a question of organisation, 3449-50. Would doubtless increase price, 3451. If in force in Copenhagen, that a small place compared with London, 3452-53.

**BOND, MR. THOMAS.** (Digest of his Evidence.)

Consulting Surgeon to Westminster Hospital, &c., 3062.

Boracic acid studied as to effects on the human consumer, 3063. Given to hundreds of patients in 10 grain doses, 3064. Given in bladder diseases for months together; no ill effects, 3065. Usual dose 30 grains per diem, 3066. Would like to know if patients were otherwise taking the drug, 3067, but not necessary to know it, 3068-69. But a medical man ought to know of any drug being taken that would modify his treatment of a patient, 3094. Physician should know if milk is boracised in cases of albuminuria, 3164-66. Gives grain doses for children in diarrhoea, 3071, 3073. Children do not have bladder disease, 3072, but the drug not unsuitable to children, 3073. Has had a few cases of itching of skin following use of boracic acid, 3074, in old men with dropsy and renal disease, 3083. Kidney disease contra-indicates large doses, 3084, 3098. Putridity of urine treated with boracic acid, 3085-86. Thirty grain doses daily would create a pronounced skin itching and perhaps some eruption, 3087. External use has led to no ill results. Case of a child sitting daily for months in a saturated solution without harm, 3097. Retards decomposition of food in the stomach; bad for irritable stomach, 3135-37, 3140, 3142, and contra-indicated therefor, 3141. But contra-indications not widely prevalent, 3144-46, 3148-54. Mortality from kidney disease not known, 3147; nor 'case fatality rate, 3150. Indiscriminate use of boracic acid might possibly hasten fatal termination of kidney disease, 3155. Contra-indicating conditions of indigestion widely distributed, 3156. Contra-indication in pregnancy not known, 3157-61, but not disbelieved, 3162. All cases of renal disease do not contra-indicate the acid, 3163.

Dose of boracic acid for a child one-fifth of an adult dose, 3076-78. Forty grains a day a limit for an adult, 3079. From 2 to 3 grains a dose for a child of five years, 3080. More would not be dangerous, 3081. Danger limit unknown, 3082.

Experiments of Dr. Annett on boracised kittens of little worth *quâ* human analogy, 3103-4.

Salicylic acid given in 10 grain doses without ill result, 3105-6; given in bladder diseases, 3107. Usual dose 30 grains a day, 3130-31. Contra-indicated in kidney disease, 3108. Delirium not known to have been produced by salicylic acid, 3107, 3110-11. Not known to be given for indigestion, 3143.

Formic aldehyde used in bladder diseases in 10 grain doses thrice daily, 3123; as a preparation called urotropine, a preparation of formic acid and ammonia; not in "Pharmacopœia," 3125-26, 3134. The chemical procedure unknown, 3127. Relation of formic acid to formalin not known, 3124. Formic acid said to be an antiseptic, 3128-29. Has not used it, 3132. Only experience is of the urotropine, 3133.

Declaration of preservatives would be a proper course, 3075, 3167, and of nature and amount of boracic acid, 3095-96, 3101, 3142, and of salicylic acid, 3109.

Quantity in use of boracic acid should be controlled; but quantities used as preservative quite harmless, 3088. About 5 grains per pint of milk quite safe, 3089; but a child might thus take too large a dose, 3090-93. Twenty-six grains per pint of milk quite unusual and unnecessary, 3099, but nothing to prevent it, 3100, and milk is liable to repeated dosage, 3102. Indiscriminate use of boracic and salicylic acids not advocated, 3112. Two grains of latter in a pound of jam harmless, 3113-14, but an efficient preservative, 3114. A pound of such jam more harmful than the contained acid, 3115. Ten grains in a quart of wine harmless; so also 10 grains in a pint, 3116; same in a bottle of cider, 3117, and in a quart of beer, 3118. Thirty grains consumed with alcohol would do less harm than the alcohol, 3119-22.

Colouring matters not studied, 3138-39.

**BOSELEY, MR. LEONARD KIDGELL.** (Digest of his Evidence.)

Analyst to Messrs. Keiller and Son, 948. Appointed primarily to determine amounts of sugar needed in jams to prevent fermentation and crystallisation, 1010. Trained by Mr. Otto Hehner, and formerly second chemist to Aylesbury Dairy Company, 971.

Dairy products (milk, cream, butter, and condensed milk) most frequently treated with borax, boracic acid, and formalin, very occasionally with salicylic acid, nitrates, and sulphites, 951-52.

Formalin is a 40 per cent. solution of formaldehyde, 952.

Milk not universally preservatives in London, but perhaps 50 per cent. is, 956. None sold by Aylesbury Dairy Company is preservatives, 1017, at any season, 1019.

Milk 10 to 12 hours old when distributed, 1022, 1024-25. Not pasteurised, 1026-27.

Use of formalin and borax equally general, 989. Has preservatives several milk samples with formalin, 990. Amounts used, one in 2000 to one in 10,000 parts; former will keep milk unchanged for months, 992, 995. The milk remains sweet, and does not curdle, 996-97. Could not testify to fitness of the milk for consumption, 1002. Cannot say as to amounts of formalin in milk, 993. It persists in milk when added, 994. Such milk would give a reaction with litmus paper, both acid and alkaline, the former if lactic acid were formed, 998-99. No samples tested for changed reaction, 1000. No physiological experiments made, 1001.

Borax added to milk in parts varying from 1 in 1000 to 1 in 10,000, 953. The latter of doubtful utility as a preservative, 954. Higher proportions were frequent, 955. Boracic acid becoming used more generally than other forms of preservatives, except in jams, preserves, and cognate articles, 986.

Butter in London preservatives to extent of 50 or 60 per cent. of amount sold. All French produce is preservatives, 957, 973-74, 976, 1013-19. Boracic acid is found in solution in the water in French factory butter, 958, and is presumably put in during churning, 959-63. No preservative in butter sold by Aylesbury Dairy Company, 975, 977-81, 1017. It comes from the Company's premises, from Wiltshire, and France, and Denmark, 1023, 1028-29; but the Company have received supplies of butter artificially preservatives, 1036-37. Has analysed rancid butters, 1003; without detecting preservatives, 1004; has made no experiments as to keeping properties of preservatives butters, 1005-8. Danish and French butters tested for preservatives, 1031; latter often contained boracic acid, 1032. Former not remembered as having yielded preservatives, 1034-35.

Cream in jugs sold by Aylesbury Dairy Company used to be preservatives; practice stopped, 981, and issue of the potted cream ceased, 1036, because of action by analysts, 1017. No preservative in their clotted cream, 982-83. Preservatives required if clotted cream is needed to keep more than two days in summer, 984. Aylesbury Dairy Company's cream partly from Wiltshire, mostly made on Company's premises, 1038. Cream sold by a large company needs no preservative, but that by small vendors does to make sale pay, 1039.

Jam makers, to extent of 50 per cent., use preservatives. Chiefly salicylic acid,  $\frac{1}{2}$  oz. to 1 cwt. of jam, or one part in 3500. Benzoic acid sometimes used, and benzoate of soda now used by one London firm, 968. No preservatives used in fruit before jam is made, 969-70; not at all by Messrs. Keiller, 1143. They would like to use them, 1,144. Messrs. Keiller's jams, except apricot from pulp, made from fresh fruit, 1009. In jam making in large quantity, under present methods, preservatives needed to keep jam several months, unless the jam be cooked to stiffness, 1084-85. Appearance is everything in jam, and cooking a short time by steam enables the appearance to be maintained, 1086. The salicylic acid is boiled with the jam, 1087. It is intimately mixed, 1088, 1092. About 5 milligrammes in 1 lb. of jam, 1089-91. Salicylic acid used of necessity in jam pulps, 1092. No instance of jam or pulp salicylised going wrong, 1093-95. Best beetroot sugar used in Messrs. Keiller's jams, 1159-60. Sugar most effective when boiled with the fruit, 1161-65.

Salicylic acid is the jam-makers' preservative, a good anti-fermentative, 986-88.

Presis.

Raspberries known to have been sprayed with formaldehyde, 970.

Preservatives not deemed necessary by Aylesbury Dairy Company, 1018; all the year round, 1019. Company supplied from distances such as Wiltshire and Cheshire, 1020-21. Not used for Messrs. Keiller's bottled fruits, which are sterilised, 1062; nor for their jams, 1143.

Sodium fluoride not a good anti-fermentative, 1046.

Deleterious action of preservatives not known, 1047-48.

Bacon and hams, treatment with preservatives only known on hearsay evidence, 1040-43. Has never determined the amount of boracic acid present, 1044.

Colouring matters in confectionery and jams, complete list of, and quantities used, possessed, 1049. List handed in, 1064-70 (App. No. 18). Reference given to experiments as to effect of colouring agents on digestion, 1071-73. No metallic colouring matters used by Messrs. Keiller. Colours used practically free from arsenic and lead, 1074. In dairying, chiefly annatto used, an extract from the plant *Bixa orellana*. In milk, in aqueous solution, one part in 300,000; in butter, in a solution of cotton-seed oil, 1050; thus used, quite insufficient to flavour milk, 1051. Red pickled cabbage coloured with 4 ozs. of sulphuric acid to a 40-gallon barrel. Piccalilli has 3 lbs. of turmeric to a 40-gallon barrel, 1056-60. Has never analysed annatto, 1078-79. Bottled fruits sold by Messrs. Keiller not coloured. In jams of dark colour, magenta or fuchsine (an acetate of rosaniline or a hydrochlorate of rosaniline) usually added in one part in 100,000, occasionally one in 75,000; vermilion usually added in one part in 80,000. These the only colours generally used, 1063, 1148-51. Health of workers not affected by the magenta, 1074, 1145-47, 1164. Composition not known or tested, 1152-58. Apricot and yellow jams and marmalade seldom coloured, 1063.

Colouring not requisite in jams, 1080; but improves their appearance, 1081. None used by Messrs. Keiller, 1142-43.

Annatto, alone, used by Aylesbury Dairy Company, 1097, 1102-4; and dissolved in cotton seed oil in butter, 1101. Aniline dyes becoming more general in milk, 1098-1100.

Martius' yellow rarely used for colouring, 1112-14; it is a poison, 1115; has never known it in butter, 1116. Imitation Demerara sugar from beetroot occasionally treated with aniline dyes, 1117. Use of iron salts and colouring of peas with copper not subjects on which he has any wide knowledge, 1107-11, 1118-27. Zinc compounds believed to be added to peas, 1128-29. Oxide of iron found in cocoa, 1130-37. May have been added as an ochre 1138. Hofman's violet used for sweets 1139-40.

#### BOYCE, PROFESSOR RUPERT. (Digest of his Evidence.)

Professor of Pathology, University College, Liverpool, and a Public Analyst of Liverpool, 2706-8, 2758, for bacteriological purposes, 2759-63.

Prosecution successful in a case of formaldehysed milk, 2709-10.

Preservatives found to be used, formaldehyde and boracic acid, 2711.

Experiments upon young kittens important; on dogs or guinea-pigs almost worthless, 2713. Kitten's digestion resembles the human, as does also its food, 2714. Cats are carnivorous, 2715. Infant's food approximates to the kitten's, 2716. Sucking pigs good for experiments; but cats and dogs most commonly used, in preference to rabbits or guinea-pigs, 2717. But certain rodents are susceptible to diseases affecting the human to which cats and dogs are not susceptible, 2718. Tuberculosis at times affects cats and dogs, 2719. Formalised milk not so appetising as undoctored milk to kittens, 2720; the same true of boracised milk, 2721, 2727-28. Kittens doubtless tend to lose their appetite for boracised milk diet, 2722. Animals used for experiments by Rideal and Foulerton too old, 2726. Continued dosage with preservative milk tends to immunity of kittens; natural immunity also comes on about three months of age, 2731. No experiments made as to bacterial growth in preservative milk, 2747-48. Bacteria grow rapidly in milk, 2749. *Bacillus coli* and *enteritidis sporogenes* present numerously in seemingly sweet milk; formalin and

boracic acid would scarcely inhibit their growth, 2750. Continued experiments on kittens yielding results like those of Dr. Annett should suffice to prohibit preservatives in milk, 2777-80.

Injury of formalised milk inferred, 2724; even in small proportion, 2725. Demonstrated as regards formalin and boracic acid in respect of infants, 2732. Inference from Chittenden's experiments on dogs in normal health that harm to adults would not accrue, 2733-34. Immunity as the result of repeated doses an argument against preservatives, 2735; because of expense at which gained, 2736. Medical men and patients handicapped by unconsciously-secured immunity to boracic acid, 2737-38. Continued dosage would be harmful, 2776. Formalin is a great irritant, even in small proportion; its action is inhibitory; it lowers the cell vitality, and has direct action on enzymes, and affects digestion through the agency of food, 2751-52, 2754-57. Boracic acid not found to irritate witness, 2752. Ammonia in certain quantities an irritant, 2753. The vapour of osmic acid also irritates, 2756. Non-irritation of formalin at a manufactory would speak well for the modern methods employed, 2771.

Declaration of all preservatives in milk not impracticable, 2764-66, 2769, and would solve many difficulties, 2767, with no great onus on a local authority, 2768. The components of the mixture should be declared, 2770, if not prohibited, 2773, 2776. Increased use of formalin would render milk unsaleable, 2774. Non-limitation of amount of boracic acid would be a difficulty, 2775.

Prohibition preferred to declaration, 2772.

Continental use of preservatives inquired about, 2729, 2739. Experiments found to be meagre, 2730, 2740, 2741 (footnote), but feeding experiments with boracic acid in milk proceeding in Berlin, 2730. Preservatives prohibited in Belgium and in Germany, 2741. No evidence of enforcement of law, 2742. Preservatives found to be used in imported American meat, 2743. Preservatives believed to be prohibited in Austria, 2745. Switzerland not visited, 2746.

#### BRIERLEY, MR. JAMES. (Digest of his Evidence.)

Public Analyst for Southampton Borough, &c., 3168.

Preservatives in food studied, 3169, and found only in milk, wine, and beer; formalin and boracic acid preparations only found save in wine, 3170. Many other foods examined, 3171, but not bacon, 3172. Use of preservatives increasing, especially in last ten years, 3173, 3207-9. Both formalin and boracic acid increasingly used, 3210, in equal amount, 3211. Preservatives not much used prior to Food and Drugs Act, 3274. Used now owing to larger demand of increased population, 3275. No relation, except in time, between the Food and Drugs Act and commencing use of preservatives, 3276-77.

Boracic acid sold largely by chemists for use in milk without instructions as to use, 3214. A good remedy for thrush, 3245. Pharmacopoeial dose not known, 3246. For young children  $4\frac{1}{2}$  grains per pint of milk, undiluted, not safe, 3247, 3250-51. Poor children not likely to get  $4\frac{1}{2}$  grains a day, 3248-49.

Formalin only should be permitted in milk. Only a small quantity is used, large doses would make the milk smell unpleasantly, 3182. Added regularly by one wholesale dealer, but only in summer, 3188. Preferred to boracic acid, 3215. Potency not known, 3216. Action inside the body not known, 3217, but not admitted as being same as outside, 3223-28. Formaldehyde, raw, has a hardening effect, like alcohol, on certain tissues, 3220. In quantity used 0.012 per cent., hardening effect must be infinitesimal, 3221. His family had used formalised milk for two years without injurious effect, 3229, 3255. Use outside milk not known, 3230. Hardening effect on fish not known, 3231. Hardening effect stated on foodstuffs would, if appreciable, affect their digestibility, 3232-35.

Experiments limited to a few persons, vitiated by idiosyncrasy, 3218. Dr. Rideal quoted as showing less interference with digestion by formalin than by boracic acid or alcohol, 3219. Milk supplies of institutions should be watched and analysed for preservatives, and notes taken as to health of children supplied with the milk, 3252.

Declaration of amount of preservative fraught with difficulty by reason of oftentimes repeated dosage of milk in different hands 3183-84. But declaration

by first handler would be a check on quantity, 3185. Repeated dosage a disinterested action, 3186, and an added expense, 3187.

Prohibition of preservatives in milk would throw much milk on dealers' hands as useless, 3179, but this is a question of organisation, 3180.

Milk outside Southampton preservatives by dissolved preparation, 100 grains to a gallon, over 12 grains per pint, 3174; in summer only, 3177. Thirty-five grains per gallon of boracic acid alone, or mixed with borax sufficient, 3175. Keeping of milk depends on home and other conditions of storage, 3176. Preservatives milk goes bad rather than sour, 3178, 3254-55. Such milk may at times be refrigerated, but is not pasteurised, 3181. Some farmers, and many large wholesale dealers, habitually preservative milk in Hants, 3188. Larger amounts added than vendors declare necessary, 3212-13. Milk samples, 118, examined in the year, and almost all would be formalised or boracised in summer. These drugs not sought in the summer months, 3236-38. Imported milk contains much larger quantity of formalin than English milk, 3239, as judged by comparative results, not by actual determination, 3240. Sample taken at the Docks, 3241, 3273. Only three samples taken, 3242-43. Quantity coming in not known, 3268-69, 3272. It was from Cherbourg or Havre, 3270-71. Lactic changes in milk retarded, and others not retarded, by added preservatives, 3253, and these latter equally detrimental, 3254. Milk need not of necessity be preservative; but it should keep 60 hours, 3256; demanding more preservative, if such be used, than would keep it for 24 hours, 3257. If practicable, a time limit of only 24 hours' keeping preferable, 3258. Delivery of milk more frequent prior to use of preservatives, 3262. Many farmers then did not supply towns with milk as such. Milk supply more copious now, 3263. Cheap milk now may mean milk and water, 3264. No greater difficulty in getting milk than formerly in enlarged Southampton, 3265. More copious milk supply as being due to use of preservatives not known, 3266-67. Now that preservatives are used, milk formerly made into butter comes to town as milk, 3278.

Cream not examined for preservatives, 3244.

Butter need not be preservative if properly made, 3189, and butter-milk expressed, 3190.

Bacon not examined, 3172, 3197-98, not an "article of food," 3199, under terms of Food and Drugs Act, 3200, and cases of proceedings not known, 3201-6.

Wine, sherry, had salicylic acid added, 3191, sufficient to vitiate compliance with "Pharmacopœia" requirements, 3192. Was a high-class wine, 3193. Sample came from London, 3194, in cask, 3195. Submitted for pharmaceutical purposes, 4 ozs. only, 3196. Preservatives not necessary in wine, 3259-60. Used only since Food and Drugs Act passed, 3261.

Colouring matter, behaving like methyl orange, commonly used for low class butters and margarine, 3279. Margarine made thus to imitate butter, 3280, and inferior butter to imitate good butter, 3281. Milk not known to be coloured in Southampton. Annatto freely used years ago, 3282. No knowledge of bad results following its use, 3283. Annatto simplest colouring agent, 3284. Used in butter as well as milk, 3285-86. Saffron also known to have been used in butter, 3292. Certain coal tar derivatives should be prohibited, 3290. Arsenic said to have been contained in them, 3290-91. Not much known of them by witness, 3293-94.

Copper in peas led to prosecutions in Southampton years back, 3287. No ill results known from eating coppered peas, 3288, or other vegetables, 3289.

BRUNTON, SIR LAUDER. (Digest of his Evidence.)

M.D., F.R.S., and nominee of Royal College of Physicians, 7423-24.

Chemical preservatives in food studied, 7425-26. Use should be regulated, because of double danger of undue use, 7427. They may enable cleanliness in milk trade to be dispensed with, 7430. Relative value and harmfulness of preservatives need to be accurately ascertained, 7431, over a length of time as to result of their continued use, 7432-36. Many of the preservatives may be as harmless as chicory in small quantity, but not in excessive quantity, 7442.

Contra-indication of borax in pregnancy, 7463, and

indiscriminate use of salicylic acid should not be permitted, 7464.

Cumulative properties of preservatives—such as boracic acid—elements of uncertainty, 7434-36.

Declaration of salicylic acid a matter of importance to patients taking it as a drug, 7464. Amount should be stated, as also as to colouring agents, 7470.

Court of Reference advocated, with specific declaration of preservatives as a basis of action as to legalisation of such preservatives, 7437-38. Medical profession should be well represented on such a Board, especially the Royal College of Physicians, 7439. Board originally suggested by analysts, 7440, and analysts requisite to its constitution, 7441. Such a Board would result in the formulation of definite rules as to preservatives, 7443. Our present knowledge as to milk trade without preservatives, a case in point of present defective information, 7444, as also in regard to sterilisation of milk, 7445. Matter of preservatives an important one to medical profession, 7456-57. Practice of physician might be stultified by their use, 7456-62. Present Committee hardly in a position to give a pronouncement as to preservatives, 7466. The Board suggested might lead to the prohibition of preservatives, 7467.

Milk can be supplied to large towns unpreservative, 7428, and should be, 7429. Cooling and sterilising would obviate need for preservatives probably, 7444. Cooling the best known form of preserving milk, 7449-51. No bad results known or feared from refrigerated milk, 7452-55. Milk supply to all hospitals should be examined for preservatives, 7465.

Sterilised milk held by some to be injurious, not so held by witness, 7445, but our knowledge may be defective, 7446-47, the raising of milk for a short time to 180° F. being in question, 7448.

Copper in minute doses quite innocuous, 7468, but it should be specifically declared, 7469. Unequal distribution in peas should hold manufacturer liable if fixed amount for whole be exceeded in any one portion, 7471-72.

CAMERON, MR. HENRY CHARLES. (Digest of his evidence.)

Produce Commissioner to the New Zealand Government, 6152.

New Zealand butter output increasing, 6155, 6214-15, and quality steadily improving, 6156, owing to instruction and inspection, 6157. Still room for improvement in New Zealand butter, 6303, and measures are taken accordingly, 6304. Butter made at dairy factories and graded by Government inspectors, 6159-60. "Factory" butter as known at home is "milled" butter of second grade in New Zealand, 6161-62. Best butter exported with salt and in many cases Preservitas, 6163-64, principally boracic acid, 6165. A little has been sent absolutely fresh, but bulk with salt, 6166, and a good deal is preservative, 6167. Milk sent to dairy factories distance of some four miles twice a day, 6185. Butter comes to England from December to May or June, 6216. Trade small in comparison with Colonial trade generally, 6228-33. Retail trade in New Zealand same as export, 6247. Butter reaches consumer in England in eleven weeks from manufacture, 6248-49. Complaints of butter have been made but kind of butter not known, 6250-51.

Margarine not exported from New Zealand, 6226, nor made there, 6227.

Price of New Zealand butter cheaper than Danish butter 6168, and butter coming over unpreservative sold cheaper than preservative butter, 6207-10.

Freezing affects butter, 6168. All New Zealand butter comes frozen, 6169, and defrosting tends to depreciation of the butter if not preservative, 6171, 6202, 6295-97.

Salt added to New Zealand butter to suit taste of consumer, 6170.

Preservatives added to New Zealand butter to aid keeping after defrosting, 6171; but not universal, 6172, on account of recent action over here. Finest butter is preservative slightly, 6173. Preservative very exactly blended with butter, 6184. Not likely to be added to milk by farmers because unnecessary, 6186-96. Preservatives facilitate New Zealand butter trade, 6203, essential to keeping the butter in the finest condition, 6204, but the trade not absolutely dependent on their use, 6205, though

Précis.

## Précis.

without them quality and price would decline, 6206. One-half per cent. of preservatives for butter quite enough, 6234-40, and satisfaction would be felt at any limit laid down, 6241-42. New Zealand Government have legislated as to preservatives, reserving the right to prohibit them if need be, 6246.

Experiment made by New Zealand Government to determine results of adding preservatives to butter, 6174; and  $\frac{1}{2}$  per cent. of preservative found beneficial for keeping butter, 3 per cent. of salt being also added, 6175-81, 6274, and preservative being boracic acid and borax, 6182, for ease of application, 6183, in powdered form, 6184. Evidence in a report of Mr. Sorensen, when Chief Commissioner of New Zealand Department of Agriculture, against use of preservatives in butter, 6252-69. Only one churning used for the experiment, 6270-73. Further experiments have been made, 6275-78, 6308-9. Conditions of uncleanness obtain still in New Zealand dairy farms, but these not held to vitiate the results of the above experiment, 6279-89. Standardising of fresh preservatives advocated, 6242.

Pasteurisation in New Zealand used to slight extent, 6179, with rather unfavourable result, 6198, 6200, by removing the finer taints, 6199, necessitating a ferment, 6200. Quality of pasteurised butter not quite as good as ordinary butter, 6201, 6294-6300, and quality goes off after defrosting, 6202. With perfect milk pasteurisation not needed, 6301-2. Pasteurisation brings up the average of butter, 6305-7.

Declaration of butter as preservative not objected to, but country of origin might suffice, 6211-13, 6243-46.

Cooling of milk compulsory in New Zealand, but not enforced according to Mr. Sorensen, 6290-93.

Colouring matter not needed nor used for New Zealand butter, 6217-22. Cheese is coloured, 6222, by annatto, 6223, exclusively, 6224-25.

## CAMERON, DR. JAMES SPOTTISWOODE. (Digest of his Evidence.)

Medical Officer of Health of Leeds, represents the British Medical Association, past President of the Yorkshire branch of that Association, and of the Society of Medical Officers of Health, 2523-25. Has been in practice, 2526.

Borax and boracic acid noticed as frequently in use in foods, especially milk and butter, 2527. Boric compounds sold freely, but not in large domestic use. Glacialine sold in sixpenny boxes, 2531. Public not generally aware of use of preservatives, 2532. Boracic acid and glacialine only boric compounds known in Leeds, 2537-38.

Salicylic acid used medicinally, acts powerfully on liver, is a depressant, usually taken in form of salicylate of soda; in large doses produces weakness and sickness, sometimes causes poisonous symptoms, 2546.

Formaldehyde not known of as a preservative, 2558. Physiological effect of preservatives is to interfere with digestive processes, 2533, 2563-69. Boracic acid given to infants for thrush, 2534. Indiscriminate use in food dangerous, especially as regards infants and invalids, for whom a medical man might want to use it, 2535. Infants might take a full dose in milk, 2536. Antiseptics have some selective action on bacteria, 2564-72. Poorer classes may suffer from boracic acid without seeking medical aid, 2583-84.

Declaration of preservatives should be made, 2557, would be useful as to coppered foods, 2578. Labelling of milk as to quantity of boracic acid would be difficult, 2580. Simple declaration would be useful to medical men, 2581, and lessen the sale of boracised milk, 2582. Colourings in food should be declared, 2587, save as to cheese, 2588-91.

Prohibition of salicylic acid should be entire, as a food preservative, 2546-47, also copper as a colouring, 2557; and of boracic acid to be preferred to declaration, 2579. Colouring in milk should be prohibited, 2592, but not in butter, 2594-95.

Milk samples taken in Leeds contained boric compounds in very varying percentages of total samples, 2528. Maximum found in milk 20 grains per gallon, 2529, five grains per quart approximately, 2530. Boracising of milk not necessary, 2579. Attitude of medical profession towards boracised milk will depend on finding of the Committee, 2583.

Condensed milk samples found to contain boric compounds, 2528.

Diarrhoea increasingly prevalent in Leeds, despite measures of precaution adopted, 2539, 2586. Some suspicion attaches to boracised milk, 2539, 2573, but no investigation made, 2577, 2585. There is a children's hospital at Leeds. Precautions as to milk not known. But stringent clause as to fever hospital milk. No boracic acid found in it, 2540-44. Diarrhoea most prevalent in autumn, 2574, when preservatives are most used in milk, 2575, going chiefly to poorer classes, 2576.

Butter samples found to contain boric compounds, 2528.

Port found to contain boric compound, 2528.

Copper frequently found in peas, 2527. Copper a poison, 2533, 2553; to some extent cumulative, 2554, 2600; but not quite like lead, 2556. Experiments made lead to inference that the digestive system may dissolve the copper in preserved peas, 2549-50; results conflict with Professor Fraser's evidence, 2551. Copper held in peas as an organic salt of copper, 2552. Copper a slow poison, with probably delayed results never definitely traced, analogous to plumbosolvent water poisoning 2553. No cases of copper poisoning under observation, 2556. Copper as a colouring should be prohibited, 2557. Peas would naturally remain in alimentary canal some 24 hours, 2559, during which digestion would be progressing, 2560, and absorption of copper would go on, 2561. Food remains in the stomach some two or three hours, 2562. Would not habitually eat coppered peas, 2596-98, and would warn patients against them, 2599.

## CASSAL, MAJOR CHARLES EDWARD. (Digest of his Evidence.)

Public Analyst, Fellow of the Institute of Chemistry, &c., &c., &c., 3783-86.

Public Analysts should be placed in a position wherein they can speak on the authority of Governmental decisions, on the question of the relation to health of added preservatives and colouring matters in food, 3788. Poisons and drugs not defined by statute in relation to foods, 3789-94. The law as it stands presents practical difficulties as to preservatives and colouring matter in the public interests, which latter are the reason for the Sale of Food and Drugs Act, 3794.

Milk supply of London needs no preservative, 3803. Cold treatment suffices, 3804. And drugs should not be permitted for the relief of the small vendor who is an undesirable milk seller, 3805. Milk should be sold in a pure and satisfactory condition or its sale relinquished, 3806. Cold storage necessary, 3807, in very hot weather, 3862, and possible with small traders, 3808. More adulteration of milk in poor districts, 3809-12. Milk of London hospitals found to be boracised, 3821. Cold treatment immediately after milking would suffice under all ordinary circumstances, 3862. All farms should have a proper water supply, 3863-64.

Cream needs no preservative, 3804, 3819. Highest amount of boracic acid found was 0.291 per cent. of boron-trioxide per lb., 3817, and lowest, 0.104 per cent. per lb., 3818. Medical men now prescribe cream in place of cod liver oil, &c., and hold use of preservatives to be a dangerous practice, 3820. In a case of boracised cream before the courts 0.464 per cent. of crystallised boracic acid present, 3852, fine inflicted, and notice of appeal given, 3853-54.

Butters examined, but origin not known, 3814. Heavy percentages of butter found to contain boracic acid, 3850-51.

Preservatives in widespread use for keeping foods saleable, and for palming off stale, inferior, and even bad articles, 3802. Substances chiefly used in milk are drugs, and are boracic acid, borax mixtures, or solutions, salicylic acid, formaldehyde; in some cases benzoic acid, probably as benzoate of soda, and boro-fluoride. All are foreign ingredients, and are liable to be added in needless quantity, 3812. Preservative chemicals unnecessary in food, 3813, and objectionable, 3816.

Boracic acid in milk held by witness to constitute adulteration, but not so held by Local Government Board. Boracic acid equal to 59 grains of boron-trioxide and 101 grains of crystallised boracic acid found per gallon of milk, 3816, 3865. Boracic acid

found in a variety of articles, 3816. Smallest quantity determined in milk was equal to 19 grains per gallon of crystallised boracic acid, 3817. Boracic acid often found in mixtures of margarine and butter and in margarine alone, 3852. No difficulty now in estimating amount of boracic acid in milk, 3866, by a process of blank experiments, 3870-71.

Salicylic acid found in a variety of articles, 3816. Found in wines, in port wine in varying quantities up to 3.15 grains per gallon, 3822. It is a foreign ingredient, 3823-24. In sherry 1.6 grain per gallon found. Large amounts found in so-called British wines, 3824. An amount like 0.7 grain would have little preservative effect on port; would probably be present as the result of blending, 3825. Cheaper wines most preservative. Has found 26.6 grains per gallon in orange wine, 11.55 grains in British sherry, 4 grains in black currant wine. Prosecution, that failed, in case of orange wine, 3826. Found in beer occasionally; 7 grains per gallon in bottled beer, 4.76 grains in Pilsener beer, 3827. Not many samples of beer examined, 3828. In lime juice 70 grains per gallon found, 3829. Some lime juice found free from it, 3830, and unnecessary hence inferred, 3831.

Formaldehyde found in milk, skim milk, and separated milk, 3816. Formalin a 40 per cent. solution of formaldehyde, a dangerous substance even in small amount, injuriously affecting digestion and having very hardening properties as shown by experiments, 3831-32. Negative evidence not of much worth in face of positive evidence, 3833. Strength of 1000 used in experiments, 3834. Such proportion recommended for food four years ago, 3835-36. Quantitative determination not yet possible to witness, 3837, 3866, but 1000 might be determined by colour process, 3867-69. Objects to use of 1000 formalin in milk, but not aware that milk with 1000 formic aldehyde is undrinkable by reason of taste; holds the contrary view, 3875-77 and footnote.

Benzoic acid found in wines, 3816.

Digestive properties of food must be injuriously affected by effective preservative drugs, 3813, 3872; and by any amount of formaldehyde sufficient to preserve milk, 3873-74.

Experiments in and outside human body not on same plane, 3872.

Poisonous substance or one having active character as a drug should not be used in food, 3794.

Declaration of composition of an article should be made, 3794; and compulsorily demanded if preservatives deemed necessary to cheapness of commodities, 3802; and should include nature and amount, 3858, and their probable effect, 3859-61; but less desired than prohibition, 3875. Practical difficulties in way of amounts being stated, 3878, and in precise determination of these amounts analytically, 3879-81, especially if a limiting value were insisted on, 3882-85, as to boracic acid, 3886, and more so as to formalin, 3887-98.

Prohibition of preservatives advocated, 3815; other than common salt, 3855, including saltpetre in the prohibition, 3856-57.

Refrigeration and sterilisation proper methods of food preservation, though perhaps more expensive, 3816.

Proceedings ending in convictions have been taken in a number of instances, 3795; but necessity of proving injury to health is a difficulty, 3796. Prejudice of customer not now found to be a difficulty as to proof, 3797-99. Expense of procedure is a difficulty with certain local authorities, 3800-1. Certain multiple forms of statement in regard of contained preservative held to be necessary to satisfy the court, 3817.

Colouring matters present difficulties; some are unobjectionable, as for butter; others, as for margarine, are fraudulent, 3838-41; as also for milk, though not for cheese, 3842-43. Aniline dye used for milk. Sugar at times fraudulently coloured, 3844, 3850; charcoal used for sweets. Various dyes from sugar and sweets used on silks, and shown to Committee, 3847, aniline dyes being in question. Dyeing test to silk often required to detect colourings, 3848. Nothing but caramel should be present in sugar, 3849, and it does not dye, 3850.

Prohibition of injurious colouring matters should be absolute, e.g., sulphate of copper in vegetables, ferruginous earthy matters, oxide of iron and in-

ferior aniline dyes in sweets, 3844-46. Copper sulphate a known poison, 3846. In one sample of sweets 0.34 per cent. of oxide of iron found, 3847.

Précis.

CLEMENT, MR. THOMAS. (Digest of his Evidence.)

Represents the Scottish Provision Trade Association, 1500, relative to dairy produce, 1502. Has 15 years' experience of the provision trade, 1501.

Butter requires the use of preservatives, especially Australasian butter, 1503-5; latter known as "Colonial butter," 1506. Butter as a rule consumed within a month of leaving the refrigerator, 1544-45. But sometimes kept over for months, 1546.

Boracic acid advised in Canadian butter, 1506, 1552-53; it is not universally used, 1507; one per cent. of preservative, that is one-half per cent. of the acid, ample to keep butter, 1518. Has a distinct flavour in butter, 1519. Prohibition would seriously affect the butter trade. Used in Australasian butters, 1527-28. Components believed to be borax and boracic acid, 1529. Manufacturers guarantee 1 per cent. as containing one-half per cent. of boracic acid, 1530; would be surprised to learn that the preservative consisted of eight-tenths of boracic acid, 1531. Presence in butter detected by taste, 1532-34, even one-quarter per cent. if the butter not keeping, 1535. One-half per cent. of preservative the average in Colonial butter, 1536. Presence not always detectable, 1537-39. One per cent. detectable, 1540. Rancidity of butter would kill the flavour of the acid, 1541-42, but could not be veiled by it, 1543.

Salted butter would not be tolerated. Margarine would replace it if insisted on, 1520. Big difference between salt and fresh butter, 1556.

Canadian butter, refrigerated, does not stand the counter as well as Colonial preservative butter, 1508-10.

Irish butter has greatly improved of late; with less moisture it would surpass Danish butter, 1510.

Danish butter has deteriorated, 1510, especially in flavour and texture, 1511, but is drier than Irish, 1512. Commands best price, 1513, and claims to have no preservative, 1514. Has lost its keeping qualities, 1516, by reason of pasteurisation, 1517.

Argentine butter, some fine, some not, 1515. Contains preservatives, 1516.

Margarine sometimes contains preservatives, 1522, but not in winter, 1523-24, only in summer, 1525.

Fresh butter for immediate use, not preservative, 1526.

Fresh butter is unsalted butter in the trade, 1560-71, 1573-79, 1581-82. It may be many months old if preservative, 1572. It is not fresh-made necessarily, 1580. Trade interests lie in furnishing the public wants, 1576-79, 1583. Refrigerated butter does not stand like preservative butter, 1508-10, 1546, even when also preservative, 1547. Such butter if kept may prove dangerous, 1547-51.

Declaration of preservative in butter not objected to *per se*, 1554-55, but not necessary, 1557-58; but the consumers' interest should be paramount, 1559.

COPEMAN, MR. JOHN WALTON. (Digest of his Evidence.)

Represents London Chamber of Commerce, 1195; has been in preserved food trade 12 years, 1167; has known preserved pea trade some 18 years, 1244-45.

Preservatives mostly used in grocery trade are salt, saltpetre, sugar, oil, vinegar, and glucose, 1169-70. No experiences of modern antiseptics, 1171. Preservative action of copper-sulphate slight, 1189. In jam, sugar and colouring matters used, 1231.

Colouring matters used in anchovy sauce, 1178. Notification of use of artificial colourings would not lead to consumption of fruit in natural state, 1179-80. Coloured vegetables fairly well used, 1181-82. Colouring used in jam, 1231.

Carmines used in France for glacé and crystallised cherries non-injurious, 1178.

Copper in small amount used in France for green-gages non-injurious, 1178. Sulphate used for peas, beans, spinach, and mixed vegetables, 1186. These goods unsaleable unless greened, 1184-87. Chlorophyll not a successful substitute, 1188. Amount of copper sulphate in peas varies from 2 to 2.8 grains per lb., 1190. One part in 10,000 in parts of Switzerland and Italy. Labelling alone required in certain American cities, 1191. Actual amount of copper contained known to be stated

## Précis.

in America, 1222. No restriction in France, 1193-94, (App. No. 21.) No case of poisoning by coppered vegetables known, 1197, 1201-3, 1263, 1274, 1297-98. (App. No. 22); but the question of proof one of difficulty, 1264. No evidence of illness, 1198. No complaints known from London Clubs, &c., 1292. Fixation of maximum quantity of copper allowable advocated, 1199, specially on account of magisterial action, 1200, 1206-8, 1285. Some people have a prejudice against preserved foods, 1204-5. Quantities of metallic copper found in peas in France, 1209-14 (App. No. 20.) Analyses made in 1896, 1215, 1217-18. Minimum quantity requisite, about 2 grains per lb. of peas, 1240-43, 1253-56. Restriction to one-half this quantity would be impracticable, 1267. Maximum quantity desired about 2.7 grains of copper-sulphate per lb. of peas, 1215-16, and used in Kent, 1266. Larger quantity used in peas than in other vegetables, 1219-21. No copper naturally in peas though it is present in beans, 1220. No objection to labelling goods as artificially coloured; nothing more deemed necessary, 1222. Even this is not necessary in many cases, 1229. No objection to amount being stated, 1223-28, 1303-4. Medicinal use and doses of copper, 1260, 1299, 1302. In Germany brown peas used generally; in parts of France peas stewed *au naturel*, 1232. Copper prohibited in Germany, 1233. Peas may be two or three years old before consumption, 1234. After that they deteriorate, 1235. Preservation of colour for three months would be useless for trade purposes, 1236-37. Has no knowledge of actual manufacture of coppered peas, 1238-39, 1273-74. Has known the trade some 18 years, 1244-45. No difference noticed in colour of preserved peas in that period, 1246-47. French peas for home use and export differently treated with copper, 1249-52. Foreign laws as to coppering of peas have changed, 1249-52, 1271. Quantitative analyses of coppered peas not trusted, 1256-57. Copper not always evenly distributed in peas, 1258, but not a very strong poison, 1259. Strongly coppered peas would be uneatable, 1260-66, 1296. Colour-keeping properties of peas with  $\frac{1}{2}$  grain of copper sulphate per lb. not known, 1268, 1272, nor tested, 1269. No objection to such experiments being made, 1270. No one would eat more than  $\frac{1}{2}$  lb. of preserved peas, 1275, no one likely to eat 1 lb., 1276. If 5 ozs. of peas were consumed, not more than 1 grain of copper sulphate would be taken, 1301. Dry marrow-fat peas largely used for soup, &c., 1277, 1279; used whole, 1278. Public will have peas green, 1283-84, 1286-88. Prohibition of sulphate of copper in peas would ruin the business, 1285. Greened peas in every restaurant in Ostend, in common use in Belgium, 1289. Greened peas fairly bright, 1290. Peas seven or eight years old thick and cloudy, 1293-94. Coppered peas not known to go off colour, 1296. Medical evidence in litigation cases considered of importance, 1305-6.

Sulphur used in dried fruit trade for bleaching raisins, apricots, plums, &c., 1172. Sulphur sometimes flavours the fruit, but keeps it a good colour, not known to be harmful, 1173; added to bloom of Carlsbad plums, and a small amount is used in champignons, 1174-76. Coloured goods generally preferred, 1280, and demanded, 1281.

Cochineal used freely in jams, jellies, &c.; it is non-injurious, 1176. Used in preserved cherries, 1178.

Sulphuric acid in jams and preserved fruit never heard of, 1177.

Turmeric used in piccalilli, &c., non-injurious, 1178.

Saffron is used, non-injurious, 1178.

Annatto (Spanish) used in butter and cheese, non-injurious, 1178, 1282.

## CORFIELD, PROF. WM. HENRY. (Digest of his Evidence.)

M.A., M.D., F.R.C.P., Medical Officer of Health for St. George, Hanover Square, &c., 5070.

Preservative effects of salicylic acid and boracic acid specially studied, 5071. Salt is a constituent of the human body, 5085. Pyroligneous acid and saltpetre also used as preservatives, 5086. Preservatives likely to lead to neglect of cleanliness, 5113. Dairies, &c., Order needs enforcement, 5114. Preservatives to be avoided as not food, 5123, and should be judged harmful in the absence of evidence, 5124-25, that is, they should be proved harmless if use allowed, 5126-27.

Salicylic acid found chiefly in lighter kinds of wine, including British wines, with some prosecutions, and in light beers, 5072. Used externally the acid is an irritating substance, 5073, a most undesirable substance in food, 5074. People ought to know they are taking it, 5075. Continuous use possibly cumulative, 5076-77, and hence more seriously effective, but acquired immunity possible, 5078-79.

Boracic acid should not be used unknown to people in food, and should not be used in milk for infants and invalids, 5075. Probably only a certain quantity can be voided daily, 5080, and any larger dosage undesirable; the acid not being a food, 5081. Overdosage likely, 5082. Dose reduced by 50 per cent. in last edition of British Pharmacopoeia, 5090. Used externally, but fallen into disuse for internal purposes, 5091. Got now elsewhere than in prescriptions, 5092. Some medical men still use it and believe in it, 5138-40, as a drug, 5141-44.

Prohibition of boracic acid desirable unless proved absolutely harmless, 5083, in all food, 5084; as also of saltpetre and pyroligneous acid, 5087. Milk trade need not suffer, 5088-89. Salicylic acid, borax, boracic acid, and soda prohibited in Austria, 5098; reasons for Continental prohibitions not known, 5099, 5100.

Digestibility of food must be inhibited if preservatives are effective, 5093, though experiments generally do not bear this out, 5094-96.

Contra-indication of salicylic acid and boracic acid in large numbers of persons, 5101-4, 5106-12, and indiscriminate use objectionable, 5105.

Milk on a different level to other foods *quod* preservatives, as being the diet of infants and invalids, 5135. Objection as regards butter not so strong, 5136-37.

Experiments on animals not of very much importance, 5115. Results should not decide a matter, 5116, 5120, such as dosing children with drugs, 5117-18. Known action of the drugs on the human economy is the point of importance, 5121, and avoidance in the absence of such knowledge advocated, 5122.

Diarrhoea not known as associated with the use of preservatives, 5128-32.

Colouring matters not much studied, 5133-34.

## CRIPPS, MR. RICHARD AUGUSTUS. (Digest of his Evidence.)

A fellow of the Institute of Chemistry, practising as an analyst at Hayward's Heath, 1932-35, 1968-72.

Boracic acid studied as it has effect in foods, 1936. Effect on digestive ferments studied as regards boracic acid, 1937-39, and as regards that substance only, 1974. Boracic acid in 1 per cent. solution has no detrimental influence as far as chemical experiments show upon salivary digestion, 1940, 1944. Not familiar with Weber's and Chittenden's experiments nor aware of their different results 1941-43, 1948. Boracic acid has no retarding influence on peptic digestion, as shown by experiment, 1944-47, nor on the rennet ferment, 1952. Borax has not the same action as boracic acid, 1949. Using zymine as a digestive agent showed slight retarding influence on digestion of strong boracic solution, 1952. The physiological action of boracic acid upon the system should determine the question of its use as a preservative, 1952, 1954-55, 1959. Experiments outside the human body not generally of much account, 1955. Phases of experiments described, 1940, 1944-47, 1951-52, 1960-67.

Milk should be free from preservatives, 1954, 1957.

Butter and cream as boracised would not affect digestive processes, 1958.

Colouring matters not studied, 1974.

## DALE, MR. HENRY. (Digest of his Evidence.)

Is an Alderman of Cork, and represents the Cork Butter Exporters' Association, 237-38.

Butter heavily salted not now in demand, greater uniformity of butter called for, 241-42; and secured, 245; mild cured butter largely prepared solely for English market, 263; especially for South England, 264; most of it exported to a distance is in hermetically sealed tins, 272; and will keep a long time, 273, 277, and is sometimes sent without any preservative, 274; but salt is used, 275, though not a heavy amount, 276.

Salt has given way to preservatives in butter, 243; unsalted or lightly salted butter would not keep for twenty-four hours in hot weather without some preservative, 265.

Boracic acid is the base of all butter preservatives, 243, 269; it is called Preservitas, 271, and is mixed with the butter, 244, 251, 278-79, 318-20; three-quarters per cent. used constantly, 250, 290-91, which dissolves, 282; butter thus treated will keep three or four months, 292; less than one-half per cent. will not do, 287-89; no stipulation made to suppliers that preservatives be not used prior to butter reaching blending establishment; but the butter is examined, and such addition is not likely, though possible, 321-25.

Factories for butter-making in Normandy style general in Ireland, 246.

Creameries for butter-making in Danish style general in Ireland, 246.

Preservatives prohibited in Denmark, 247; cost about four times that of the salt required formerly to preserve butter, 252-54, namely, 6d. per lb., 283; but cost is infinitesimal per lb. of butter, 284-86. No knowledge of preservatives in cream, 338.

Prohibition of preservatives in Irish butter would affect its keeping quality, 248; and injure the trade, 256.

Danish butter consumed more quickly than Irish butter, 249; held to be of closer texture than Irish butter, 257; and to contain less water, 258; proportion imported very large, 260; owing to adoption of improved methods of manufacture, 261-62; it contains some salt, 265; it deteriorates if kept long, 300; but it is mostly consumed on arrival, 301-2; but travels far afield in competition with local produce, 313-15; additions of preservatives locally under these circumstances not known, 316-17.

No complaints of use of preservatives, 255.

Irish butter trade regaining lost ground, 261, 297; and much butter equal to Danish, 262; compares with Normandy butter as to saltiness, 265; if Danish method adopted in Ireland the producer would be handicapped, especially in hot weather, 298-99; much Irish butter is shipped on chance of sale, 301; a good deal comes to London, 303-5; it contains 12-13 per cent. of water, 306-7; there are seasonal variations from 10 to 23 per cent., but no standard, 308-9; excess of water may go to determine the reason for preference for Danish butter, 310-12.

Normandy butter, preserved by wrapper soaked in preservative, would absorb the solution, 266; this method tried by some shippers, who also added preservative to the butter, 267; exclusive use of Normandy system not known, 268.

Colouring matter added to butter, 281, 326; only needed in Irish butter in winter, 327; fluid colouring used, saffron not now much used, though presumably one of the chief components, 328-29; colouring tested, but name not known to witness, 330-33; saffron and annatto were both used, and best retentive colour decided upon finally, 334; only vegetable colourings used, 336-37; no aniline dyes used, 337.

Period of transit from Cork and Denmark to England practically similar, 293-96.

DAVIDSON, MR. WILLIAM. (Digest of his Evidence.)

Represents Scottish Provision Trade Association, as to hog meats in relation to preservatives, 1586.

Preservatives not used in the cure of meats, apart from salt and saltpetre, 1586-88, 1610. Necessary in hog products consumed by mill hands in heated atmospheres, 1588. Salt foods hurtful to such hands, 1599-1600. Less taken when much salt used, and more cheese eaten, 1601-3.

Borax used for sprinkling on outside of acon and ham, after cure, and washed off on arrival. Not used in hung hams, as it would permeate the meat. Any hams penetrated by borax not sold as fine meat, 1588-89. Should not be used for meats intended for hanging, 1615-19. Has known it to penetrate an inch, 1590, when put on moist meat, 1592, 1611-12. People would not eat borax-flavoured ham, 1591. Penetration tested by smell, 1604-8.

Australasian butters expected to contain preservatives, 1593; and believed to do so, 1597-98. Trade seasonal only, 1623-24, 1626-27, owing to climatic conditions, 1628, and sometimes output small, 1630, on account of drought, and lack of grass, 1631.

Danish butter accepted as containing no preservatives, 1594. Believes it contains some, 1595. Will have some analysed, 1596. Has lost its keeping qualities by reason of pasteurisation, 1596, 1614. It is an all-year-round butter, 1624-26. Cows housed eight months a year, 1629, and no food scarcity exists, 1630.

Taint of bacon is in interior of meat and has a flavour different to borax, 1608-9.

Cure of hog meat less prolonged than formerly, 1613.

Bacon trade a week-to-week trade, 1620-21.

Fresh imported meat not preservative, 1632-33, but mildly cured on arrival in brine only, 1634.

DE HAILES, MR. ALFRED JAMES. (Digest of his Evidence.)

Analyst to the Dairy Protection Society, and their representative, and a Fellow of the Institute of Chemistry, 3899-3902, 3944-45, 4027-30.

Milk transit to London practically limited from a distance to two trains daily, morning and midnight, and morning's milk 24 hours old when it reaches consumer, 3903-7, 3948, and evening milk 12 hours old, 3908-13. Hence milk should keep some 24 to 36 hours, 3914, and requires some method of preserving it, 3915, and a boron base preservative is the best and safest, 3916. To restrict, as fresh milk, the sale of milk not fresh would be a hardship on distant milk-service vendors, 3939-40. Distance an important factor in regard of use of preservatives, 3948-49.

Small traders tend to be crushed out by organised trade, 3946-48.

Butter in Denmark unpreserved now as a matter of protection against Irish competition, 3986-92, 3998-99. It was boracised until recently, 3993-98. Danish butter does not keep long, 4019-22. It is pasteurised, and hence acquires a distinct taste, 4023. Keeping quality of butter depends on use of preservatives, 4025-26.

Cream trade would cease if preservatives were forbidden, 3984, 4033; all London potted cream is preserved, 3985. Cream keeps three days without preservative, 4034, 4036. Potted cream for trade purposes should keep a fortnight, 4035.

Preservatives largely used for milk in London, 3923-25, distance being an important factor, 3926-27, and present trade demands a preservative, 3928-29. Formalin and boron-base preservatives mostly used, 3930, the former being easy of application, 3931. Preservatives are necessary in both milk and butter 4003, 4016-19, but distance of source of milk all-important, 4004-9. Preservatives in milk the lesser of two evils, 4031.

Cold storage will keep milk fresh for some considerable time, say, milk cooled to 40°, 3917, 3950; many farms cannot cool to below 60°, 3917. Many farmers have not got cold water, 3918-21, 3951-56. Some of London milk trade does not use preservative, 3922. Preservatives the only cheap method of safeguarding milk, in view of absence of cold water at many farms, 3957-63. Cold storage would render preservatives in milk unnecessary to large communities, 4010; not so cooling of the milk, 4011. Aylesbury Dairy Co.'s procedure not known, 4012-15. Cold storage milk vendors are against the use of preservatives, 4031.

Pasteurisation and sterilisation change the character of milk, 3964-66, 3972-75, and the change may have grave effects on children and invalids, 3976. Continental general use of cooked milk not known, 3982-84.

Formic aldehyde should be prohibited in milk, 3966-68. Purchaser prejudiced by formaldehysed milk, 3969-70.

Boracic acid effects no change in milk, 3970, and milk boracised is hence fresh milk, 3971. No harm known to have resulted from boracised milk, 3976-81. Borax factory workers enjoy phenomenal health, 4036-41. Boracic acid recommended for use in milk in "Applied Chemistry," issued nine years ago, 4041-43.

Declaration of preservatives in milk impossible, and objected to, 3932-35. Not aware of system in United States, 3936-37, and notice to all customers impracticable, 3938, as also with butter, 3941-43. Labelling impracticable, 4001, and if declaration were alternative to prohibition, the latter would have to be enforced, 4002.

Prohibition of boracic acid in force in Austria, 4006.

Précis.

Précis. DUNN, MR. CHRISTOPHER J. (Digest of his Evidence.)

Represents Cork Butter Market Trustees, 3010-12  
Butter sent to Cork seldom preservatised, 3013;  
factory butter has preservative added, 3013, 3015.  
Preservative generally some soluble borate of soda,  
3013, 3051. Despite advice to use 1 lb. of preserva-  
tive per 112 lbs. of butter but little Cork branded  
butter is preservatised, 3014. Foreign butter com-  
petes with Irish butter; Australasian butter takes  
the place of the old Irish winter trade butter, 3016,  
3050. Danish butter largely pasteurised. One Cork  
Creamery also pasteurises. Factory butter could  
not be pasteurised, 3017. Doubtless much Danish  
butter is factory butter, 3018. Nothing in quality  
of Irish butter to necessitate a preservative, 3023.  
Irish butter keeps well; not so dry as Danish, cer-  
tainly not so dry as Australian butter. Question of  
water investigated thoroughly by Munster Agricul-  
tural Institute, 3024, 3037-38. Results showed that  
dry salted butter keeps just as well as when mixed  
with warm pickle, 3025-26. Fresh butter not in  
question, 3027. No salt in fresh butter, 3028.  
Keeping depends on expulsion of butter-milk and  
water. Common belief that mountainous country  
butter keeps best, 3029. Keeping not affected by  
amount of water present, 3032-33. Reputation of  
keeping properties of Danish butter unknown, 3034.  
Danish trade for quick consumption, 3035. Irish  
salted butter used to be stored for months; public  
taste has altered this, 3036. Water normally present  
in Irish butter, 14 or 15 per cent., 3039. If 18 per  
cent., butter not Cork branded, 3040, 3044; if 20  
per cent. prosecution used to and might still ensue,  
3040, owing to proceedings of like sort in Man-  
chester, 3041-42. Over 18 per cent. would betoken  
negligence, 3044-46. Pressing out of water requires  
great care in hot weather, 3047; but very cold water  
in skilled hands would ease matters, 3048-49. Pre-  
servative frequently mixed with salt first, 1 lb. to  
100 lbs. of butter, 3051, 3053. That quantity could  
not be added in the form of pickle, 3052. Con-  
siderable proportion of Cork trade passes through  
the Market, 3054. A very large industry, 3055.  
Declaration of use of preservatives would not be  
objectionable, 3019-20.  
Prohibition would not permanently affect the butter  
trade, 3018, 3021. It would serve the purpose of  
the home trade some think, 3021. Others dread  
prohibition, 3022. It would not greatly or long  
alter prices, 3050. Trustees of the Cork Market  
differ on the point, 3056. The Australian and  
Canadian butter would have to come frozen, 3057.  
Cold storage would in large degree meet the case,  
3058. Difficulty as to Irish butter would lead to  
cold storage and frequent local demand as essentials,  
3059.  
Medical considerations should outweigh those of  
trade, 3060-61.  
Colouring of butter going out. Only saffron and  
annatto known, 3030. Highly coloured butter,  
demand declining, 3031.

UPRÉ, DR. AUGUSTE. (Digest of his Evidence.)

Doctor of Philosophy, Fellow of the Institute of  
Chemistry, Public Analyst, and F.R.S., 5901.  
Cleanliness may be discounted by the use of pre-  
servatives in milk, 5902-3. Guarantee of cleanli-  
ness lost when preservatives added to milk, 5905.  
Indeed dirt is cloaked by such addition, 5942-47.  
Milk of paramount importance *quâ* preservatives as  
being in cases an entire diet; not so butter, 5906.  
Fish should not be preservatised, 5907-12.  
Preservatives objected to on principle, 5903, and indis-  
criminate admixtures of chemicals to food, 5904,  
irrespective of their effect, 5905.  
Colouring matters of a poisonous nature should not  
be employed, 5913, in any quantity, 5914. Colours  
should be classified, 5918, and poisonous colours  
entirely prohibited, 5919. Harmless colours not  
objected to, 5931, but proof of character should  
precede use, 5932.  
Quantitative analysis difficult in cases, e.g., boracic  
acid, to determine precise quantity, 5920.  
Declaration of colours should designate poisonous  
colours as such, 5921. This would go a long way,  
5937.  
Prohibition of fraudulent colouring, as of "mixtures"  
and the like, advocated, 5938-41.  
Copper in peas should not be allowed, 5915, 5917.  
Practice ceased some years back; now in force  
again to meet public demand, 5916. Effect of

1 grain per lb. of peas unknown. Some people  
idiosyncratic to minute quantities, 5922-25, and  
idiosyncrasy is very common, 5926-30. Colouring  
of peas scarcely fraudulent, 5933-36.

FABER, MR. HARALD. (Digest of his Evidence.)

Fellow of the Chemical Society, 4199, and Agricul-  
tural Commissioner to the Danish Government,  
4200-2.  
Declaration of preservatives should be made if they  
are permitted, 4203-4. Saccharine in beer and wine  
allowed in Denmark only if declared on the label,  
4206.  
Objections to preservatives lie in their chemical cha-  
racter, and action *quâ* decomposition of food in the  
human economy, 4205.  
Preservatives not used in Danish butter, that is, in  
one-half of total foreign butter trade of England,  
4317.  
Prohibition of salicylic acid, boracic acid, and certain  
mineral salts in wines and spirits in Denmark, 4206,  
including salts of aluminium, barium, strontium,  
and magnesium, 4207. Salicylic acid prohibited  
since 1886, 4208. That and boracic acid prohibited  
as injurious to health, 4208-9, 4266, 4354-56, it being  
felt also easier to prohibit borax in butter prior to  
its use becoming general, 4267, and thus probably  
dangerous by use in many articles of diet, 4268-70.  
Only common salt allowed in dairy produce in  
Denmark, and no inconvenience results, 4210-11,  
even in Copenhagen, 4212-15. Prohibition of borax  
in butter had rather a present element of injury to  
trade, though a probable prospective advantage,  
4271-75.  
Norwegian and Swedish practices as to preservatives  
not known, 4312-15.  
Butter in Denmark preservatised to a small extent  
only, prior to prohibition of preservatives, 4219-20,  
and then only by boron base preservative, 4263-65.  
Most butter is salted to some extent, 4221. Some  
sent not salted, some  $\frac{1}{4}$  per cent., but most about  
1 per cent., 4222. Pasteurised butter adjudged the  
best, 4309-11.  
Keeping quality of Danish butter keeps it for a  
minimum of some three weeks, 4223, 4277, in  
summer, and much longer in winter, 4318-22, for  
some seven weeks, and then it is sold as fine fresh  
butter, 4323-26, at top price, 4327-31. Price hangs  
on many factors, 4332. Results of experiments as  
to keeping quality promised, 4339 (App. No. 26).  
The butter not improved by preservatives, 4225, if  
butter well made, 4226. Nearly exclusively made  
of pasteurised milk, 4227, by reason of an Act aimed  
at checking the spread of tuberculosis in cattle,  
4228. Keeping quality as good as ever, 4276. Some  
butter will be three weeks old on reaching retailer,  
4278-79. being salted butter; saltless butter con-  
sumed more quickly, and only some 2 per cent. of  
whole export trade, 4280. One per cent. of salt will  
keep butter three weeks, 4281. The more water the  
poorer the keeping power of butter, 4282. Some  
14 per cent. of water in Danish butter on shipment,  
4283, some of which evaporates in transshipment,  
4284. Probably more in Irish butter, 4285-89,  
though no necessity for it, 4290, and probably little  
difference in well-made Irish butter, 4291-95.  
Normandy factory butter drier than Danish, 4301.  
Its flavour varies, 4302, and the finest goes to Paris,  
4303.  
Soil, vegetation, or food generally does not affect  
flavour of butter; but the bacterial life does, 4296-  
99, and pasteurisation obviates all "feed taste,"  
4300. Flavour is produced by fermentation, 4304-5,  
4308, not by breed of cattle, 4306-7, 4333.  
Trade in Danish butter not affected by preservatised  
French and Irish butter, 4224. It is about half of  
foreign butter trade of England, 4316.  
Sterilisation of milk by two large firms in Copen-  
hagen, 4216, 4258, by pasteurisation; and cream also  
treated thus, 4217, in 97 per cent. of dairies, 4231,  
even before requirement that cream be pasteurised,  
4309, and milk heated to 185° F., 4218. Pasteurisa-  
tion does not interfere with flavour of butter, 4228,  
but colour test can distinguish pasteurised butter,  
4229; not so the palate, 4230. It helps fermenta-  
tion, 4231. Does not flavour milk unless the milk  
be heated to over 85° C., and need not flavour it,  
4248-49; a matter of rapid cooling, 4250, even  
with 90° C., 4251-53. Raw milk avoided in Den-  
mark; many people boil any unpasteurised milk  
purchased, 4254-55. Vending of pasteurised milk

not the rule, 4256-57. One town demands that milk be pasteurised or drawn from cows which have stood tuberculin test, 4258. All towns have power so to rule, 4260-62. Necessity for pasteurising milk only related to prevention of cattle disease by tuberculosis, 4227-28, 4259. Pasteurisation medically recommended, 4331-36. Milk very often boiled on Continent, 4337-38. Perhaps 25 per cent. of Copenhagen milk supply pasteurised, 4340-43, and milk brought from distances of 120 miles, 4345-46. Infantile mortality of town not known, 4344. Milk cooled prior to train journey, 4347-48. Cost relatively to large trade small, 4349. Small farms cool with water, and factories or dairies with ice, 4350-52. Committee would be welcome to see Copenhagen method of treatment; that of Pasteur Milk Supply Company commended, 4353. Reference to bouquet of cream as produced by fermentative agents promised, 4357-59.

Bacon from Denmark a large trade, 4232. No present regulations as to preservatives, but prohibition intended in meat products generally, 4233, on ground of injuriousness, 4234. Borax only used, and that in limited amount, 4235, and it does not penetrate from outside, 4236. Injection of solution of salt containing borax is made into the meat in curing some bacon, 4237-40. Percentages given of salt in certain Danish, Irish, Dorset, and Wiltshire bacon, 4241-42, according to which injected meat might contain 0.4 to 0.8 per cent. of borax, 4243.

Agricultural pursuits occupy about half Danish population, 4244-47, in 1890, about  $\frac{1}{3}$ ths, footnote to 4247.

FISHER, MR. WALTER WILLIAM. (Digest of his Evidence.)

Public Analyst, President of the Society of Public Analysts, and represents that Society, 4710-15.

Boracic acid not common in fresh meats; sometimes used in sausages; more commonly used in salt-meats, German sausages (under  $\frac{1}{2}$  per cent), bacon, and ham (from  $\frac{1}{3}$  to  $\frac{1}{2}$  per cent). Found by Dr. Dyer in only one of 270 milk samples, 4717, but in 30 of 234 butter samples, averaging under  $\frac{1}{2}$  per cent., two being over 1 per cent., 4717-21. Over 100 grains per gallon found in milk, and conviction obtained, 4736, 4762. Boracic acid is used recklessly, 4763-64.

Preservatives commonly used in dairy products, 4717. Not necessary in milk in rural districts, 4749, and none used as a rule, 4751; not needed in Oxfordshire, 4750.

Formalin, in milk in very small doses, as affecting the organism, not known of, 4723, 4738, but harmful properties suspected, 4730-31, to the point of withholding its legalisation in milk, 4767, until more is known of it, 4768. Effect on peptonised milk for invalids suggested as a matter for inquiry, 4743. Quantitative determination of formalin in milk accurately impracticable, 4753.

Hardening effects of formic aldehyde known, and dangerous properties pointed to, 4754-60, 4765-66.

Meat extracts generally free from preservatives, also potted meats, outside salt, 4717.

Sulphurous acid found in British wines, vinegars, pickles, &c., probably harmless as used, 4746. Beers not examined for years, 4769-70.

Restriction on the use of preservatives desirable, 4726, 4737, boracic acid in milk being instanced, 4728, and a superior limit called for, 4732, though some difficulty might arise in cases, 4733-35, and especially as to formaldehyde, 4741-42, at present, 4752; limit should be placed on preservatives on salted and preserved meats (as ham and bacon) and fish, 4745.

Declaration of preservatives should be made in some cases, 4726, as in milk if permitted, 4728. No resolution passed by Society of Public Analysts, 4744. Declaration of milk as formaldehydised would not guarantee against a harmful dose, 4761.

Prohibition of preservatives should be enforced in some cases, 4727, and entirely in new milk, 4728, and new cream, fresh fish, and fresh meats, 4745. No resolution passed by Society of Public Analysts, 4744.

Colouring matter, red ochre, used in bloater pastes; German sausage skins sometimes dyed, 4771, 4775-77. Nitrites poisonous in large doses, not as used for meats, 4771. Some meat preservatives are coloured, 4772-74. Some colourings named, 4778. Tem-

perance drinks coloured, 4779. Chromate of lead and oxide of iron known to be used, 4780. Jellies coloured, 4793, with small quantities of colouring, chiefly yellows and reds, 4794.

Copper in peas in an unsatisfactory position, 4781. as to effects of the copper, 4782. Used probably to give green appearance to peas, 4783-85. Use is objectionable, 4786, on the ground of health, 4787. Use thought of as fraudulent, 4788-92. No experiments made, 4795.

FOULERTON, MR. ALEX. G. R. (Digest of his Evidence.)

Fellow of the Chemical Society, and of the Royal College of Surgeons, &c., 4044-46.

Milk requires preservatives to a certain extent, 4047.

Preservatives should be added immediately after milking, 4050. When now added not known, 4051-52. It is desirable to prevent bacterial activity by early addition of preservative, if allowed, 4053-57. Almost impossible for London poor to get good fresh milk, 4058, at present, 4059. Large vendors can do without preservatives, 4060. Distance an important factor, 4061, 4128. Interests of small vendor not superior to those of general public, 4062, who would not suffer if he disappeared, 4063, if milk supply could be otherwise kept up, 4064. Milk can be kept sweet by  $\frac{1}{1000}$  formic aldehyde and  $\frac{1}{1000}$  boracic acid, 4048-49, 4080. Company vending former recommend  $\frac{1}{1000}$ , 4082-85. Mr. Thompson held that  $\frac{1}{1000}$  formic aldehyde and  $\frac{1}{1000}$  boracic acid kept milk sweet for a week, 4086, at room temperature, 4087. Chief London agencies look to sanitary condition of dairy farms, 4108-11. State of farms a factor in determining the keeping quality of milk, 4112. Even if cooled, milk will not keep 24 hours in extreme heat, 4115-18, 4134-35, though it will in ordinary weather, 4119. Milk often kept in filthy circumstances in poor district houses, 4120-22, 4128, 4173, and on vendor's premises, 4170, 4173, and hence preservatives needed, 4123-25, but the conditions should be removed, 4126, 4171-72, and if this were accomplished preservatives would become unnecessary, 4127. A large milk trade in small vendors' hands, 4129-30. If Birmingham has 91 per cent. of its milk free from preservatives, that is an element against the alleged necessity for preservatives in milk, 4131-33. Vienna, circumstances of milk supply not known, 4134-36. Preservatised milk not proper for invalids, 4147, nor children, 4148. Would not allow 80 grains of boracic acid in a pint of milk, 4155. Aylesbury Dairy Company use no preservatives, 4158, and draw milk from a distance, 4159. Nothing to prevent consumers adding preservatives to their milk, 4174-75, but the poor should not be left to add them, 4176-80, but practice not personally known, 4181.

Preservatives used for other foods than milk, 4068, but not so necessary, 4069. Use does not counter-balance uncleanness, 4113-14. Any premium placed on cleanliness to be deprecated, 4137.

Boracic acid as used in milk harmless to ordinary individual, but probably hurtful in cases of infants and invalids, 4047. But  $\frac{1}{1000}$  would be safe, 35 grains per gallon for an individual taking a pint daily, 4048-49.

Formic aldehyde would perhaps render milk a little less digestible, 4047. But  $\frac{1}{1000}$  safe for ordinary individual taking a pint of milk daily, 4048-49. Not known that the Formalin Company always advised use of limit of  $\frac{1}{1000}$ , 4107. Quantitative determination not known, 4142, but probably impracticable, 4143; and hence danger arises *quid* use in food, 4144. Its use for persons on milk diet injurious, but not for ordinary persons, 4146.

Experiments made in conjunction with Dr. Rideal, 4077-78; and his work as to boracic acid and formic aldehyde known, 4079; but resulting demonstration of small effect of use of those preservatives not known, 4081. Has found  $\frac{1}{1000}$  formic aldehyde to keep milk sweet overnight in summer, 4088-91. Change of milk detected by taste and smell, 4092-95. Exact composition of sour milk not known, 4096-98. Lactic change not due to any one bacillus, 4099-4105; though lactic acid primarily in question, 4106. No taste could discriminate below 0.4 per cent. of lactic acid, 4182-84. Dr. Rideal's experiments in his Table (App. No. 24) show not the slightest effect accruing from use of preservatives

Précis.

## Précis

in milk in 24 hours, but do not determine the fact of possible unfitness of the milk for food, 4185-86. Fish died in a few hours when subjected to ~~formic~~ formic aldehyde, 4138; which is a powerful poison in undiluted form, but not poisonous as used in milk, 4139-40; but double dose in milk would lead to consumption of liquid fatal to fish in five hours; but ~~formic~~ had no effect on action of frog's heart, 4141. Normal saline solution used, 4163; and no chance of fixture of formic aldehyde occurring, 4164-66. Formic aldehyde and boracic acid as preservatives have but little effect on the digestibility of food, 4160. Digestibility of sterilised milk said to be less than ordinary, 4161-62.

Contra-indication of milk preservatised with boracic acid or formaldehyde very common, 4149; and may include healthy persons, 4150. "Preserved" milk now held to mean condensed milk, 4151. Both equally injurious for children, 4152.

Sterilisation would help to keep milk, 4070; especially if bottled, 4071; but then expensive, 4072; as illustrated by Paris hospital practice, 4073; but expense mainly a matter of management, 4074-75. Sterilisation would be beneficial in the interests of the community, 4187; but its destructive effect on the tubercle bacillus doubted, 4188-93; but the heating of milk to 65° Centigrade would be a benefit, 4194. If practicable sterilisation would be the best thing, 4198.

Germicidal action of boracic acid and formaldehyde on certain bacteria inhibitory rather than destructive, 4195-97.

Scheduling of certain preservatives to be authorised a matter for inquiry, 4167. Preservatives are a changing quantity, 4168-69.

Declaration should be made of preservatives in milk, to safeguard infants and invalids, 4047. Desirable from public health point of view, 4065. Trade interests should not stand in the way, 4066. Exact nature or amount need not be declared if officially fixed, 4067. Declaration favoured rather than prohibition, 4076.

Prohibition of preservatives or a "leave-alone" policy the alternatives if limitation of maxima impracticable, 4153-54, and the former inclined to as regards chemical preservatives, 4155-56, that is, total prohibition, 4157.

**GIBSON, MR. ROBERT.** (Digest of his Evidence.)

Salesmaster of Limerick Public Creamery Market, &c., 6310-11. Represents South of Ireland Butter Merchants' Association, 6364.

Irish fresh butter trade depends entirely on preservatives, 6312-13, and these necessary for Irish salt butter also, 6314. All butter controlled by witness is preservatised, 6328, 6373. Trade will require preservatives until defects in present system are righted, and butter is no longer required to keep as now, 6361, 6385, 6390-92, 6395-96. Danish butter contains, some of it  $2\frac{1}{2}$  per cent., and some 3 and 4 per cent. of salt, 6361-62. Salt tends to evaporate, 6363. No complaints of preservatised butter, 6374-75, but complaints of unpreservatised butter, 6376. Trade increasing in Ireland, 6396.

Keeping power of Irish saltless butter under one week without preservative, but a fortnight at any rate with preservative, 6314. Salt preservatised butter keeps for four months, 6315-16, 6376. Irish butter essentially a keeping butter; not so Danish and Normandy. Irish butter trade mainly summer trade only, 6317. It need not be so, 6323-24, as witness has endeavoured to show farmers, 6325, with some success, 6326. Danish butter all-year-round trade, 6318-19. Calving cows largely housed in Ireland in winter, 6320. Irish trade such that butter must keep for months, 6353, 6394, and does, and commands good price, some being preservatised, 6354-55. Butter experimented on kept nine months with preservative added, 6364. Irish butter keeps much longer than Danish, 6393.

Transit of butter from New Zealand under best possible conditions, 6331, from Ireland and in England under very worst possible conditions by railways and steamship companies, 6331-33, 6343-45; many complaints, 6334, and practically no redress, 6335. Specific complaints instanced, 6332-33, 6337-42. Danish and Swedish Governments see to such a matter, 6336, and get a better service, 6386-89. No improvement in handling the butter by railway companies, 6346-49. Improved transit needed, 6397.

Education of Irish butter-makers at fault; Danes well educated, 6357-60. Improved education needed, 6397.

Price of Irish winter butter higher than best Danish, 6326, 6404, some of the former being salted and some saltless, 6327.

Cold storage non-existent in Ireland, 6379, and price of ice there prohibitory of refrigerating plant for general use, 6380-84. Creameries have cooling tanks, not so the farms, 6401, and the milk travels long before cooling is accomplished, 6402-3.

Cleanliness not enforced at nor proper inspection made of Irish farms; and creameries also need looking to, 6404.

Preservative in Irish saltless butter, 1lb. to 112lbs., 6328, 6377, analysing out to 0.8 per cent., and quite sufficient, 6329, 6378, 6400; 3 lbs. of salt added make a salt butter, 6330. Use of preservatives in butter a question of rapidity of consumption, 6350. Consignees of witness know of preservative in butter, and private clients demand it, 6351. Borax and boracic acid the base of all the preservatives used, 6357. Preservatives will remain requisite till present defects of manufacture and the necessity for storage are removed, 6394-99.

Flavour of salt preservatised butter milder than such butter without preservative, 6356.

Creamery butter about  $\frac{1}{4}$ th of Irish trade, 6368-69.

Margarine made in Ireland, 6371-72.

Declaration of butter as preservatised not objected to, 6352.

Milk in Ireland in winter months sent into towns, thus interfering with butter trade, 6317, 6321-22.

Colour of butter debateable point in Ireland. Witness holds it essential to meet varying local tastes, 6364, 6369-70. Colour cannot be kept constant by food; it can by having Jersey cattle, 6366-68. Colouring enables margarine to be sold as butter, 6364, 6370.

Prohibition of colouring of butter would lead to seasonal changes in natural colour and give dissatisfaction, 6365.

**GILBEY, MR. ALFRED.** (Digest of his Evidence.)

Partner in the firm of Messrs. W. and A. Gilbey, 4360.

Preservatives, other than brandy, unnecessary in wines imported to this country, 4361, 4371, 4380. Salicylic acid heard of years ago in cheap Spanish wine, 4362, Tarragona, 4369, and known in wine-producing countries, 4363, really in inferior wines, 4364. It is a preservative, and reduces the amount of spirit required, 4365, arrests fermentation, and is easily detectable, 4366-71. Not known in this country, 4366-67, 4371-75, 4379, 4392, 4404. Light Portuguese wines not likely to be imported, unless fortified or preservatised, 4376, and not known to be imported, 4377-78. "St. Julien" made on banks of Thames extremely likely to contain salicylic acid, 4381-86. Mineral acids in wine not known, 4405-6.

Prohibition of salicylic acid in wines contracted for by Messrs. Gilbey, 4362, the acid also being prohibited in many wine-producing countries, 4364, 4380, including France, 4370. Formaldehyde also prohibited by Messrs. Gilbey, 4368. Their wines tested for preservatives, 4396, 4403 and footnote.

Colouring matters, other than grape juice, not needed in wine, 4361. "Colour wine" used, but little colouring matter, 4387, 4393. Alum not known, 4388. Probably burnt sugar and glucose in liqueurs, 4389. Salts of copper, picric acid, or cochineal not known, 4390-91. No excuse or need for colourings even in cheap wines, 4394-95. Messrs. Gilbey's wines tested for colouring matters, 4396-4403 and footnote.

**GREGSON, MR. CHAS. E. L.** (Digest of his evidence.)

Represents the Liverpool Provision Trade Association, 856.

Borax and boracic acid not used thirty years ago; borax used in small amount twenty-five years back; it is now driving out salt packing; mild cured meat required by the public, 858. Borax packing keeps it mild, 894-95, and free from slime, 896. Borax used for 75 per cent. of American and Canadian meats, 859, 876. Neither borax nor boracic acid used in curing meats, 864. Borax applied to surface of meat after curing, 865, in a dry state, 866, and only so, 891-93, 900-1; it remains dry, 929, and is all washed off over here 867, 869-70. Its retention would flavour the meat,

868. Application to meat closes the pores, 871. Taint and fly-blow obviated by use of these preservatives, 873, 881-82. Taint generally a matter of bad or imperfect curing. Borax will not save meat that has gone bad, 916-18. Taint occurs before cure is complete, and fly-blow afterwards, 919-90. No complaint of borax-packed meat except by the trade recipient when borax had not been completely removed in washing, 874. One per cent. used and needed for preservative purposes, 877-80, 883-87, 1 lb. per cwt. of ham, 924. Borax expensive, 887, about 6 or 7 cents per lb. in America, salt being 30s. per ton, 888. Borax would keep meat a month in reasonable weather, 889-90. It is not absorbed, 898-99. Pumping of solution into meat vessels not known, 902-3. Borax not advocated, but used because demanded, 903.

Prohibition of borax would curtail the bacon trade, 875.

Injury to health from boracised meat unknown, 915.

Salt used now for packing 25 per cent. of American and Canadian meats, 859, which come hard-salted for the Irish trade, 860-61, but even Irish trade in mild cured meats is growing, 862. Meats packed in salt arrive too salt for public taste, 871, 875, 896. Salt is absorbed by the meat, 897, 931-33. Percentage of from 5 to 10 used in cure, 927, and even 20 per cent. if hard-salted meat needed for Ireland. A good deal of the salt runs to brine, 928.

Pickle curing used for some American meats, 865, known to be pumped into meat vessels, 902-3.

Bacon and ham from America might possibly be cured this side by the use of refrigerators; the experiment has, however, failed commercially, and it is risky for the meat, 905-8, 921-23; cost also is against it, 909-13.

#### GRÜNBAUM, DR. ALBERT. (Digest of his Evidence.)

M.A., M.D., M.R.C.P., and Lecturer on Chemical Physiology in the Liverpool University College, 6405-6, 6481.

Continental legislation as to food inquired into, 6407; principally in Germany and Austria, 6408; as to preservatives in food, 6409.

Prussian ministerial circular totally prohibitive of preservatives in food, 6410; and local bye-laws made in the same sense. Preservatives in milk totally prohibited, 6411, 6413-14, 6432; as also in wines, 6411-12. Milk dealt with on account of impossibility of fixing standards for the Kingdom, 6415; and because harm from use of preservatised milk was feared, 6433-34; especially as to children 6435. Proceedings taken at Hamburg and elsewhere as to preservatives in milk, 6416-17; and as to sodium sulphite in minced meat, 6418; the substance being injurious to health in small amount, 6419-20. Germany seeking to prohibit preservatives in meat, 6423. Experiments were made as a basis for existing legislation, 6436-38, 6442, 6465. Formalin used, but very rarely found, 6439; the same as to salicylic acid, 6440; as regards milk, 6441. Expert evidence has been taken in Germany as to results following the administration of sodium sulphite, 6442, 6445; even in small doses, 6447; namely, headache, diarrhoea, indigestion, and catarrh, 6446. Found in minced meat, a food for invalids, from 0.08 to 0.86 per cent.; not found in milk, 6444-45, 6447. Medical profession against preservatives, 6457-58; on general principles, and as not knowing when patients were taking them, 6459. Berlin milk supply unpreservatised, 6459-62. Distribution in closed vessels, 6470-72; and in bottles in the smaller towns, 6473-74. Evidence as to preservative legislation mainly concerned with milk and minced meat, 6466. Preservatives forbidden in beer in Germany, 6467, 6469. Milk sent by rail in ice-cooled vans, 6477.

Copper sulphate in peas held in Germany to be harmless in amount required, 6448-49, and not prohibited in minute quantities, 6450-51. Laws of other countries not known, 6452-56.

Vienna has bye-laws prohibitory of preservatives in food, milk being especially in question, and sodium carbonate being included in the prohibition, 6421-22, 6464. Ministerial decrees in Austria prohibit specified preservatives and colouring matters, 6426-27. All preservatives are prohibited in milk, and Hungary is seeking to prohibit all preservatives, 6428. Present action in contemplation in Austria not known 6429-30. In Vienna only one sample of

milk in one year found to be preservatised, and that by a large quantity of sodium carbonate, 6463. Preservatives forbidden in beer in Austria, 6468-69. No evidence as to use of saccharin procured, 6475. Switzerland prohibits borax and boracic acid in imported meat, 6423-25.

Preservatives should be prohibited, as injurious to cells of the system, 6476, 6478; in other substances as well as milk, and including sodium sulphite and boracic acid. A septic rather than antiseptic food should be aimed at, 6477. Digestion at times affected by preservatives, 6479.

Declaration of preservatives advisable, 6480.

Experiments on animals valuable on certain defined lines, monkeys being preferred to cats or dogs, 6482, and with positive results as to preservatives, 6488-90. But, weight for weight and age for age, animals stand unnatural food better than the human, 6482-83. Pig said to approximate to man in structure, 6484-87.

#### HALLIBURTON, PROF. W.D., M.D., F.R.S. (Digest of his Evidence.)

Professor of Physiology, King's College, London, F.R.C.P., and nominee of Royal College of Surgeons, 7525-26.

Physiological experiments form the basis of evidence to be given, especially as to boron compounds and formaldehyde. Continuous use of antiseptics objectionable on general principles, 7528. Even salt immoderately used has been injurious, 7529-30. Germicidal substances hostile to man in food, 7528-30. Economy of dog more resistant than that of man, 7565-66; metabolic processes of dog and puppy much the same, but diet varies, 7567-68. Experiments of Dr. Annett not known, as to boracised kittens, 7569-70.

Borax and boracic acid have caused skin eruption and dyspepsia, 7541-49. Borax more readily soluble than boracic acid, 7543. Admixtures of both commonly used in the form of glacialin, 7544. Harmfulness of continued use of borax on kidneys held. Mal-nutrition of infants fed on boracised milk instanced. Digestibility of milk interfered with by minute doses of borax, but not of boracic acid, 7545, 7548. Milk that kept good with borax added, went bad with a similar quantity of boracic acid, 7546-47. Borax a more efficient antiseptic than boracic acid, 7548. Liebrich's pamphlet on the action of borax thought of as biased, 7558-64. Boracic acid least harmful of preservatives, 7578-79. Experiments of Foster and Chittenden known; latter shows boracic acid as innocuous in certain quantities in the case of dogs, 7591-94.

Formaldehyde a marvellous antiseptic and inhibitive of digestion in minute quantities, 7548. Is absolutely opposed to its use, 7572; and the indigestibility of food by its use held to be proved by experiments *in vitro*, 7583-85. Commercial formaldehyde known to be used in milk in 1900, 7586-88. Would not flavour the milk, 7589-90.

Salicylic acid effects little known by witness, 7571.

Prohibition of all foreign substances as admixtures in food to be desired, 7530, 7573-77. May be difficult, but is ideal, 7578. Prohibition of formaldehyde should be absolute, 7548, 7550, also of salicylic acid, a dangerous drug, 7551-53. Nitrate of potash should be prohibited, 7576.

Declaration the alternative to prohibition of preservatives; it would meet the case of idiosyncratic people, 7532-33. Borax should be notified, 7542; important to the public generally, 7543.

Cold storage to be preferred to preservatives for food, 7530-32.

Sterilised milk not known to be harmful, 7580-82.

Pasteurisation of milk likely to alter and render less digestible the proteids in milk, 7601-14, but any specific toxic action brought about by boiling of milk must be very slight, and if existing should have been discovered long ago, 7614-21. No poisoning effect to be feared from re-arrangement of inorganic phosphates in milk, 7622-23.

Copper accidentally in canned foods, apart from its use as a colouring agent, 7534-38. Harmfulness of copper in peas depends on quantity used, 7554. Copper in peas to be condemned, 7555, 7557, as a foreign substance, and cumulative; no copper normally in the human body, 7556. But no experiments made by witness, 7595-96. Cumulative effects likely to become increasingly harmful, 7597-7600.

## Précis.

Colouring milk caused dyspepsia in an infant, 7538. Better to avoid artificial dyes, 7539; though public taste known to be arbitrary, 7540.

Fish unfit for food rendered saleable by use of boracic acid; danger is marked, 2278.

Meat, fresh, dusted with borax; evil results have followed, 2280.

## HANDFORD, DR. HENRY. (Digest of his Evidence.)

Honorary Physician to Nottingham General Hospital, Consulting Physician, Medical Officer of Health for Nottinghamshire, 2259-62.

Boracic acid as a food preservative studied, 2263. The acid used in a variety of foods doubtless, 2281, and risk thus run by consumers, 2282.

Dose of boracic acid for adult, 10-15 grains, and for infant 1-15th of that, 2270. Has prescribed it moderately, 2289. Intermittent medicinal dosage recommended, 2290, owing to very frequent complaints of discomfort caused by its maintained use, 2291. Would not use it in nephritis, 2292-93. Action on uterus not known, 2294. Has given it for epilepsy; appetite failed, 2295. Would object to a fever patient having any boracic acid, 2302-4. A medical man should know if a patient be already taking any boracic acid, 2305.

Cooking would equally distribute powdered boracic acid in milk, 2274.

External use made of boracic acid as a lotion and dressing said to have led to bad results; has not himself seen any, 2283. Relatively harmless as an external drug, 2264.

Internal use of boracic acid shows it to be an irritant and cause of loss of appetite, 2264; in sickness, probably also in part in healthy individuals, 2265. Thirty grains a day taken by some persons for long periods with apparent impunity; others get discomfort in a few days. Some continue drug, notwithstanding its unpleasant results, which come and go as its use is maintained or omitted, 2266. Use in stomach not known to have caused ill effects, 2284. Gastric disturbance has followed its use for cystitis, proportion of cases not known, but from 20 to 40 per cent., 2285-87.

Contra-indication of boracic acid not alone in fever, but always save when direct benefit from the drug is expected, 2303.

Prohibition of preservatives in milk might in great measure be absolute, if cleanliness were ensured, 2276; and cold storage adopted, 2322. Dairies, &c., Orders need enforcement, 2323-24.

Declaration of boracised milk impracticable, 2275.

Preservatives increasingly in use, but not much known to medical men, 2277; including boracic acid, 2296-97; hence results of use not generally known, 2298, or traced, 2299. Other preservatives not studied, 2300-1.

Diarrhoea in a child seven months old, held to be related to boracised milk, 2267; not a crucial case, 2311-12. Two pints taken daily by child, 2268, and some 7 grains of the acid, 2269; a heavy dose for the child, 2270. Milk free from boracic acid substituted, 2271, and child slowly got well, 2272. Effect of change of milk not studied in other cases, 2314-15. Such dosage could only have prejudicial effects, 2273. Diarrhoea read of as caused by boracic acid, 2288.

Milk in children's hospital found to contain 28·96 grains of boracic acid per gallon. Its use discontinued, and unpreservatised milk contracted for, 2267, as the result of observation in one case of diarrhoea, 2313. Decomposed milk disguised by boracic acid, 2278. Milk should not be boracised, 2302-4, 2319. Milk putrid more harmful than if sweet and moderately boracised; but such putrid milk would not be purchased, 2306. Putridity would be checked and veiled by boracic acid, 2307. Both the acid and the ptomaines might be taken, 2308. Their corrective action not a reasonable assumption, 2319. Milk for the poor and rich in regard of guarantee of freedom from preservatives not on same footing, 2310. No experience of ptomaine poisoning by milk, 2316-17. Boracic acid would not neutralise effect of ptomaines, 2318. Milk would not be recommended by medical men in large quantities unless guarantee of freedom from boracic acid were assured, if its use were sanctioned, 2320, with mischievous result from such restricted milk diet, 2321.

Cream increasingly in use for infants and invalids. Boracic acid largely used in it, 2278. Not known how added, 2279. Has heard of powdered particles being visible, 2280.

## HARRIS, MR. JOHN MITCHELL. (Digest of his Evidence.)

Deputy Chairman of the Bacon Curers' Association, &c., 5948-50.

Bacon of Wiltshire brand cured by Harris and Co., of Calne, 5951-53. Salt and saltpetre used in the cure, 5954, and these alone, 5955. English bacon trade very small compared with American trade, 6015-17.

Borax packing used in American and Canadian bacon trade, 5961. If it does not get into the meat no harm done, 5962. No experience of the practice, 5964, nor of the trade, 5966. American bacon cured with salt and saltpetre and packed in borax, and this borax washed out over here, 5967. Borax not used for curing in home trade, and rarely in Ireland, 5979. Borax not personally objected to, 5980. French conditions as to presence of borax in imported bacon not altered, 5999, as experience has shown recently, 6000, but rather they are stricter, 6001. Temporary withdrawal not known of, 6014. Borax has no aroma, 6004-6. Much the larger part of bacon coming to English consumer is borax-packed, 6018.

Declaration of borax should be made, 6035, and would do away with present injustice to English bacon trade, 6036.

Smoked bacon would not do from America, 6037-38. "Smokine" known, but not used by best curers, 6039-41.

Penetration of meat by sprinkled borax demonstrated by experiments, 5968-78, 6019-27.

Price of Canadian bacon the inducement to buy it, but English curing of bacon greatly on the increase, 5981-85. American bacon goes mostly to poorer districts, 6018. Price of bacon if borax prohibited would only be affected as mode of carriage increased in cost, 6028-33. If America and Canada charged English prices they would sell no bacon, 6034.

Mild-cured bacon possible without the aid of borax, though perhaps nothing better known for use from America, 5986. It can be so produced and exported, 6007. Injection of borax in brine very seldom made, and quite unnecessary, 5987. Mild-cured bacon was possible before preservatives came in, and trade now all year round, 6002-3. It is exported to greater distances than America, and in a state fit to go to the seller, not in a green state like the American exported meat, 6008-9.

Export trade of Harris and Co. large, 5956, 5988, but larger part of trade is home, 5989. Dried bacon packed in salt, 5957, in canvas bags in dry salt in cases for India and the Cape, 5958-59. No occasion found for borax packing, 5960. Canvas keeps out the salt, 5963. Method quite satisfactory, 5965. Bacon sent abroad is a little more salt and extra dry, 5990. Sent to India, Cape, China, &c., 5991-92, 6010, to hot climates, by steamship, 5993, probably in cool chamber, 5994. It is packed in the hold, 5995-96, and is in high temperature in many cases, 5997. No complaints received, 5998. Boracised bacon sent abroad from America by way of England, packed like English bacon, 6011-13.

## HATTERSLEY, MR. I. A. (Digest of his Evidence.)

Managing Director of Aylesbury Dairy Company, 5766-67.

Milk supplied to Aylesbury Dairy Company from distances up to 200 miles, 5768-70, 5846, even in summer, 5847, and free from preservatives, 5771-72, as being unnecessary, 5773-76, and from a protectionist policy many years ago perhaps, 5776. Stipulations as to non-use of preservatives with contracting farmers, 5776, 5882-83. Only 78 letters of complaint as to sour milk out of upwards of five million deliveries, 5776-77, 5875, and these chiefly owing to improper treatment of milk by customer, 5832. No difficulties of transit by rail, 5778. Milk occasionally sent in a fish truck, 5779-80. Precautions adopted to secure proper milk supply from farmers, 5818-19, and farms inspected, 5820. Churns sealed during transit, 5824-26. Trade of Company 1½ million gallons yearly, 5841-43, from 50 farms, 5844, averaging 50 miles away, 5845. Some 100,000 persons supplied annually, in 14,000 households, 5848-53, over a wide London area,

5894-95. Milk comes to Paddington and Euston, 5896-97. Many poor-class customers, 5898. Milk rarely required to keep more than six hours after delivery to houses, 5878, or customer would scald it, 5880. Treatment in house important *quâ* keeping power of milk, 5881, 5899. Some nursery milk delivered in bottles, 5884-86, from special farms, 5893. Bottled milk entails expense, 5887-88. Paris has bottled milk, at 6d. per quart, 5889. Copenhagen gets both bottled and can milk, 5890-92.

Cooling of milk on milking insisted on, 5781, as essential to its keeping, 5782, 5821-24, also straining, 5819. Water supply of farms traded with looked to as proper, 5827-31, also the sanitary condition of the farm, 5830, 5882-83, 5899-5900. Cooling of milk only at fault once in 1899, 5832-34.

Pasteurised milk has little demand, 5783-84, milk heated to 160° F., 5785.

Sterilised milk demand increasing, 5784. Milk heated to 212° F., 5785, and fairly large trade done by Aylesbury Dairy Company, 5786. Delivered in bottles, 5885.

Cleanliness of milk churns ensured by treatment by Aylesbury Dairy Company before return to farmers, 5786.

Cream collected by Aylesbury Dairy Company in London, except one supply from Sussex, 5787-88. No preservative used, 5789, even in clotted cream, 5791, also made in London, 5792. Only one verbal and one letter of complaint of cream per 2,000, and 20,000 quarts respectively, 5790, and less frequent relatively than as to milk, 5872-78. No preservative required for Devonshire clotted cream sent to London, 5793. Clotted cream keeps longer than ordinary cream, 5794-95. Grocers sell cream because they can preservative it, 5854-56.

Butter churned by Aylesbury Dairy Company contains no preservative, 5796-97. Imported French butter contains a preservative, 5797. It is a factory butter, 5798-99. Preservatives seem necessary to Normandy saltless butter, 5800-1, 5835, system at fault, 5836. Fresh butter sales increasing, 5837, Company's sale doubling in five years, 5838. Why not known, 5839-40.

Margarine not dealt in by Aylesbury Dairy Co., 5806.

Colouring matter used by Aylesbury Dairy Co. to secure continuity of colour all year round, 5802, 5804-5. Would be glad to be able to do without it, 5802, in milk, 5815. Customers demand coloured milk, but little colour used in summer, 5803, and will have it, 5857-60. Repeated attempts to do without colouring milk have failed, 5861. Complaints have followed its temporary disuse, 5866-69. Colouring of margarine by the trade neither honest nor desirable, 5806-13; does not hurt the Company's butter trade, 5814. Has no opinion to offer as to the colouring of cheese, 5816-17.

HEHNER, MR. OTTO. (Digest of his Evidence.)

Public Analyst and Fellow of the Institute of Chemistry, 5562-63.

Preservatives in food extensively studied, 5564. Nearly always boric compounds in cream, 5584. Not necessary in food generally, and misleading to the public, 5593, 5634-35. Originally used in butter collected from farmers in small quantities, 5595. Regulation required of quantities of preservatives permissible, 5605, in gradually diminishing amount in butter, as facilities to obviate their use come in, 5606. Nitrate of potash not to be condemned, rarely met with, 5636. Drugs objected to as preservatives. Salt is a food, 5637-38.

Boric acid tastes butter, and public palate is getting seasoned thereto, 5605. The only preservative to be condoned in any way, 5614, and solely in butter, in annually diminishing quantity to vanishing point, 5615. Probably three-fourths of imported butter preservative, 5616-19, 5631-33. Boric acid prohibited in butter used in France, 5619-22. Used for meats, ham, bacon, sausages, herrings, &c. 5623-27.

Formalin never found in butter, 5610. As a preservative should be prohibited, 5611. Personal experiment therewith, ~~5606~~, resulted in illness, 5612-13. Milk samples largely free from preservatives, though both formalin and borates found, 5576, that is in country milk, 5577-79. No necessity for preservatives, 5580, 5607. Milk of a large London dairy company free from all preservatives, 5581. Preservatives in milk should be prohibited, 5608.

Cream as sold by milkmen rarely preservative, 5576, 5581. Cream from grocers almost always preservative, 5582-83, always boric compounds, in many cases 56 grains per lb., 5584. Grocers' trade in cream calls for preservatives, 5585-88, and induces them to use them, 5589-91, and mislead the public as to keeping quality of cream, 5592.

Butter samples numerous examined for preservatives, 5564, and 90 per cent. contained them, 5565, always boric compounds from very small quantity to 1 per cent., 5566. Butter which reaches the consumer quickly needs no preservative, 5594-95. Bulk of fresh butter goes to better class, 5596-98. Demand for saltless butter may have to do with use of preservatives, 5599-5600; but some butter, e.g., Danish, free from preservatives, and practically also from salt, 5600-1. Danish butters good, and command a high price, 5602, and no difficulty arises in vending them, 5603.

Margarine requires no preservative, 5599, 5603. No need for boracic acid, 5604.

Prohibition of preservatives in milk should be absolute, 5608, and preferred as to butter, but deemed difficult, 5609.

Colouring matter much used in South England butter, some uncoloured in Midlands, 5567. Aniline colour now much used, in very small quantity, 5568-69, not sufficient to harm, 5570. Martius' yellow never detected, 5571. London milk almost invariably coloured, 5572, 5574-75. Deceptive practice, but universal, 5873.

Copper in peas a poison, perhaps not injurious in quantities used, but use fraudulent and should be prohibited, 5628; limit of safety not so easily overstepped as with some poisons, 5629, but copper sulphate has a point where it becomes distinctly poisonous, 5630.

# HILL, DR. ALFRED. (Digest of his Evidence.)

Medical Officer of Health and Public Analyst of Birmingham; represents the Incorporated Society of Medical Officers of Health, 2325-27.

Analyses made of various kinds of food, 2330-31. In 1896-99 20 per cent. contained preservatives, 2385.

Milk samples from 1896 to 1899 in 9 per cent. of number contained either boracic acid or formic aldehyde, 2332, 2385, 2461-63. Quantitative analyses made, 2333. Of milk samples in 1896 there were 83 per cent. boracised, 2334. Boracic acid decreasingly used, and formic aldehyde increasingly used, 2340, 2383-84. Of milk samples from farmers 2 per cent. contained preservatives, 2341. Milk most frequently preservative in summer, 2343, 2389-93. Same sample found to contain boracic acid and formic aldehyde, 2381-82. Use of boracic acid may have reference to supply and demand, 2394-96. Preservative samples most frequently adulterated, 2397-98. Watered milk does not need a preservative more than other milks, 2399, 2400. Old milks naturally would be preservative, 2401-4, and fraud perpetrated therefore, 2405-8, and danger arise by decomposition, 2409. Lower classes most likely to get preservative milk, 2450. Incipient harmful changes in milk not perceptible to taste or smell, 2467-69. People will drink milk slightly sour, 2471. "Fresh" milk is milk recently from the cow, 2502-3, and unpreservative, 2504. Preservative chemicals in milk disapproved of by the Society of Medical Officers of Health, 2522.

Butter samples to 28 per cent. in 1896-99 contained boracic acid; 31 per cent. in March quarter, 23 per cent. from April to September, 2344, 2385; latter by reason of fresh butter being in summer use, 2345-48, and locality of supply, 2472-74. Birmingham summer supply largely local, 2472, and in winter Continental, 2474. Australian butter contains no preservative, 2475-77. It comes in cold store, 2478. "Fresh" butter is unsalted butter, 2507, and may be months old, 2508-11, and customers still be unprejudiced by the title, 2512-14.

Margarine samples to 84 per cent. contained boracic acid, 2349, 2385. Why, not known, 2388. Remainder free from all preservatives, 2350. Often sold as butter, 2351.

Meat foods to 64 per cent. contained boracic acid, from 10 to 45 grains per lb., 2352-53, 2385, 2410-14. Acid mostly was intimately distributed, 2357. Quantity did not vary greatly, 2358. It might be visible, 2359-60. Taste would reveal it, 2361.

Miscellaneous food samples, cream, jam, vinegar, to 33 per cent. contained boracic acid or salicylic acid,

Précis.

- 2362-63, 2385; 9 samples boracic acid, and 12 salicylic acid. Thick cream, 5 samples; 4 boracised, and 1 salicylised; 3 clotted cream all boracised; of 11 skimmed milk, 1 boracised; of 12 malt vinegar, 1 boracised; of 6 jams, 5 salicylised; of 12 sherry, 1 weak in alcohol, salicylised; of 11 ipecacuanha wine, 5 salicylised, 2364. Latter therefore not pure, 2365; a serious offence, leading in Wolverhampton to prosecution, 2366. No prosecutions in Birmingham on this score, 2425-35. Proportion of salicylic acid not known. Cream contained 24 and 42 grains of boracic acid per lb. Separated milk, 28 grains per gallon; malt vinegar, 14 grains per gallon, 2367. All samples taken in Birmingham, 2369-70.
- Ham and bacon boracised by external rubbing or laying on, 2354. Samples examined as retailed, 2355. Boracic acid pervaded the whole ham, but most was outside, 2356-57.
- Boracic acid found in 1896 in from 21 to 126 grains per gallon of milk, 2334. Various reasons for differences; carelessness, mixture, addition in solution, and in powder, 2335. Added generally by wholesale purveyor, 2336, farmer, or middleman, 2337. Three separate additions may be made, 2338. Poisoning by the acid not known, 2415. This acid most frequent preservative in foods decomposed and also preservative, 2436-40. A day's visit to Birmingham might result in more than a maximum Pharmacopoeal dose (45 grains) of borax in food consumed, 2456-57, plus a like medicinal dose, 2458-59. Indiscriminate treatment of food with borax hampers the medical profession in the treatment of patients, 2460.
- Formic aldehyde present in milk 1000000 to 1000000. Often believed to be 1000000, 2333. A dangerous preservative, 2342, 2418-20, 2443. Never used for butter, 2350, 2439. Stronger than boracic acid; used in smaller amounts, 2386; and more efficacious, 2441-42. Injurious effects not known, 2387, 2416-17.
- Benzoic acid or salicylic acid never found in butter, 2351. Poisoning by latter acid not known, 2416-17.
- Prohibition of preservatives; no general action taken by Birmingham Town Council, 2328, or to regulate their use, 2329. Prohibition absolute as to milk in New York State, 2452-53; also in Belgium and Austro-Hungary, and parts of Switzerland, 2454. The same feasible for Birmingham, 2455. Boracic acid unnecessary in milk, 2461-66, 2470. Use of preservatives should be prohibited by law, 2499-2500, 2506; use disapproved of by Society of Medical Officers of Health, 2522.
- Declaration should be made of addition to, and quantity of preservatives in milk, 2505, and indeed in all foods, 2522.
- Cold a better preservative than drugs or minerals 2500-1.
- Prosecutions for boracised milk successfully undertaken, 2341. Also as to butter, 2367. Not taken against wholesale dealer, 2368. On ground of injury to health of preservatives, very difficult, 2424-32.
- Physiological effects of boracic acid marked and hurtful, even fatal. Use of drug requires regulation, 2339. Inconvenience from use of preservatives in food has arisen on many occasions, 2372. Hearsay instances quoted, 2373, but none known personally, 2423. Injury has followed internal use of the drug, 2421-22. Preservatives prejudicial to digestive processes, 2511, 2515-17. Haphazard administration most dangerous, 2518.
- Diarrhoea thought of in relation with boracic acid in milk, 2374, 2448-49. Causal relationship not studied, 2375, 2447, or traced, 2445-46. Investigation would be difficult, 2376. Poor people most liable to diarrhoea, 2377, and to get boracised milk, 2378-80. Several causes of diarrhoea can always be found, 2444. The disease increases in the ratio of poverty, and among the class getting most preservative milk, 2450-51.
- Colouring matters studied a little, 2479-80; preserved vegetables, mostly free from colourings, 2481-82. Those not coppered less green, 2483. Health should not be sacrificed to colourings, 2483. Sulphate of copper injurious colouring agent; a harmless colour should be employed. Pickles not coloured, 2484. Aniline colours used in milk at times, and at one time in spurious Demerara sugar. Also annatto in milk, and possibly turmeric. Chromate of lead not now used, but used to be found in confectionery 2485-86.
- Confectionery and milk colourings now harmless. Milk in Birmingham vended by one man with yellow coloured water in cart, 2487-88. No proceedings feasible, 2489-91. None taken in Birmingham as to coloured peas, 2492-93. No experience as to legal dealings with injurious colourings, 2494-95. Specified metallic colouring matters prohibited in certain countries, as Belgium and France, 2496, and should be so at home, 2497-98.
- HOPE, DR. E. (Digest of his Evidence.)
- Medical Officer of Health for Liverpool, 6821.
- Preserving of food to be desired and waste prevented, 6822-23. Cold storage and chemical preservatives two known means of preserving food, 6824. Copenhagen system of cold storage, 6824, not applicable here by reason of cost of ice and cost of inauguration, 6825. System failed in Liverpool; doubtless it has had some success in Manchester, 6826. The Copenhagen plan is worked by block ice, 6827.
- Preservatives becoming more common in every-day articles of food, 6840. Same objection does not lie as with milk and cream, 6841. Food preservative may be dirty and contaminated and yet sterile, 6867-69.
- Milk kept sweet for some time by a limited application of cold; preservatives seldom found in Liverpool milk samples, 6828. No necessity for chemical preservatives in milk, 6829, 6837, 6839. Vendors say public want them, 6838. This is not so, 6839, 6864. Liverpool milk supply comes from a radius of some 50 miles, 6831-33. Sterility of milk claimed as regards milk rendered sterile by chemical preservatives, a false claim, 6870-75. Milk at Liverpool hospital very frequently analysed, 6884, for preservatives, including nature and amount 6885-87, 6889-90. Milk should contain no preservatives, 6888, 6891, especially in fever hospitals, as digestive processes are thereby interfered with, 6892. Physician should know composition of milk taken by a patient, 6894. He might stultify himself, 6895. Milk supply of large town needs no preservative, 6896, nor refrigeration, 6897.
- Cream more commonly preservative than milk, 6834, and sold both by dairymen and grocers, 6836. Preservatives not necessary, 6835, and not approved by medical authorities, 6837.
- Borax dusted over pork coming in large and increasing quantity from America: procedure not deemed objectionable, 6878. Boracising of fish given up, 6915, because flavour was destroyed, 6916. Boracising of oysters not known, 6919. Oysters having 38 grains of boracic acid to the lb. objected to, 6920-21.
- Salicylic acid found, 150 grains to a gallon of wine, 6923, some 19 grains per pint, 6924. This would with other such things upset children, 6925, but is not a serious matter of itself, 6927-28. British wines in question, 6926.
- Sulphite of sodium in meat heard of, 6913, but not inquired about, 6914.
- Formalin heard of as used for fish, 6917, but not inquired about, 6918.
- Jam unequally preservative with salicylic acid; some has none, and some ten times that of others containing the acid, 6843. None necessary, 6844. Manufacturers probably ignorantly reckless, 6845.
- Egg powders are baking powders; one such powder is prepared with dried egg, 6853; some are not egg powders at all, yet are used by some persons as food for children, 6854, 6859-62. Some labelled as not made from eggs, 6855, as the result of a prosecution, 6856-58. Powders are coloured to simulate egg-colouring, 6863, 6865-66. Egg powders looked upon by vendors as naturally eggless, 6864.
- Indiscriminate and reckless use of preservatives objectionable; 150 grains of salicylic acid found per gallon of British wine, 6842, 6923.
- Sterilisation preferred as an alternative to chemical preservatives, 6899. Infantile scurvy never heard of in association with sterilisation, 6900-1. Evidence to the contrary as to sterilised humanised milk, 6902-7.
- Harm may accrue to young infants by use of preservative milk, by way of retarded digestion. Kitten experiments demonstrate harm by boracised and formalised milk, 6830. A case of illness in a child by one day's boracised milk diet, 6841, 6910-12. Very serious harm will result to infants if the "humanised" milk now sold as pure milk is pre-

servatised, 6879, and this may result despite practicable precautions, 6880-83. Harm looked for if boracic acid administered in scarlet fever and kidney disease, 6893. Harm to infants from preservatives difficult to trace, 6908-9. Relation of preservatives to infantile diarrhoea not traced, 6922.

Declaration of preservative, amount and nature and date of addition should be made in all cases, 6867.

Prohibition of preservatives in milk desired, 6888. Need not dislocate the trade, 6898.

Proceedings have elicited defence that preservatives as used are not a danger to health. Witness disagrees. Another defence has been their use as medicines; but the argument is absurd, and the administration of drugs in such manner is most objectionable, 6846.

Trained inspectors necessary for the obtaining of average samples of food, 6875-77.

Colouring matters sometimes ornamental and harmless. Commonest used for sausages described, 6847-48. "Smokene" also described, 6849. Use fraudulent, 6849-51. Glucose and treacle sold as syrup also fraudulent, and burnt sugar and dilute acetic acid when sold as vinegar, 6851. Latter not injurious. Colouring matters conceal staleness, inferiority, and dirt, 6852. Colourings of "egg-powders" fraudulent, 6863, 6866.

Copper not uncommon in bottled peas, fruits, and vegetables;  $\frac{1}{2}$  grain to a lb. deemed by trade necessary to green the peas, 6929. Copper as found in peas held to be soluble in human economy, 6930, on eminent hearsay evidence, 6931. Uneasiness and indigestion have resulted from coppered peas, 6932.

#### HUDSON, MR. JAMES. (Digest of his Evidence.)

(Appears on behalf of the Butter Association.)

Chairman of Messrs. Hudson Brothers, provision merchants, 489-90.

Butter trade has seen many changes during last 50 years, 492; all butter heavily salted years back, especially Irish butter; such butter not now saleable, and no necessity for it since preservatives came into use, 493-94. Any overstock of butter is cold-stored, and never spoils, 548. Cold storage in vogue for past five years, 553. Factories consign the butter to London, 495, with added preservatives, 496.

Colonial, Irish, and Normandy butter principally dealt with; no complaints of Normandy butter, 501-2. New Zealand butter from cold storage quite fresh and sweet, 504. Canadian butter has been kept three months, 549-50, when preservatives in use, 551. No complaints of butter turning off as formerly, 551-52.

Danish butter but little traded in of late, 502; it does not keep as well as Colonial or Normandy or Irish butter, 503-4; sale probably decreasing, 538; has not sold it for two years, 539-40; good firms use Colonial and Irish butter in its place during winter, 541.

Irish butter trade increasing, 538; has increased 200 per cent. during recent years, 542-44.

Bacon and ham smoked on arrival in green state, and any preservatives washed off, 506-8.

Preservatives not added to butter by Hudson Brothers, 492, 546; one half per cent. put in by factories sufficient, 492, and never exceeded, 499; butter so treated used for years, 500; one per cent. or over could be detected, 497, by the flat taste, 498, spoiling the flavour of the butter, 500. Butter taken out of cold store would turn at once if no preservative had been used, 555. Preservatives but little used in English bacon and ham, but used in American products, 505. Their use tends to increased consumption of produce, 517-18.

Prohibition of preservatives would affect both producer and consumer, 501; and injure the Irish and foreign trade, 504. Prohibition by France of American bacon and ham wherewith preservatives had been used, carried out and also withdrawn in 1899, 505, 523. Prohibition would stop the sale of cream, 515, and of Irish butter, 538.

Boracic acid, of one quarter per cent., in cream will keep it some four to six days, 515, 526-30; useful for keeping fresh meat and game, by sprinkling, 518-19, and does not penetrate, 520.

France strict as to use of preservatives and colourings, 521-22.

Proceedings against Hudson Brothers on account of boracic acid in cream, 509-11; 16 grains to the  $\frac{1}{2}$  lb., or about one quarter per cent., 512-13.

Cream unpreservatised will not keep a day in summer, 515; more than one half per cent. of boracic acid unnecessary, 526-27.

Colouring matter used in butter in winter only, 531; used in cheese unnecessarily, save to meet public demand, 533; annatto said to be thus used, 534-36. Saltpetre used for colouring bacon and hams, 508.

#### HUTCHISON, DR. ROBERT. (Digest of his Evidence.)

Assistant Physician at the London Hospital, and represents Great Ormond Street Hospital, 6691-92.

Boracic acid taken by witness, 20 grains a day, for a fortnight continuously on full stomach produced no observed ill effects at all, 6693-94, 6696-97. If witness has a weak spot it is his stomach, 6695. Also 5-grain doses twice daily of borax and boracic acid solution, 2 $\frac{1}{2}$  grains of each, for the same period had no ill results, 6698-6700, 6712. Inference that boracic acid and borax as used in milk consumed by an adult would be harmless to an average healthy man, 6701. Boracic acid excreted by the kidneys, 6706. Would not like to take 80 grains as a dose, 6713, even with a pint of milk, 6714.

Formalin pretty largely used, 6740. A local irritant, 6741. Small quantity only required to preserve milk, 6742.

Benzoic acid irritating when swallowed, 6743, in 5 to 10-grain doses, 6744, on an empty stomach, 6745, in single doses daily, 6746. Frequently prescribed for septic conditions of urine, 6747. No local stomachic irritation noticed when it was prescribed, 6748.

Contra-indication of borax in kidney disease not a matter on which would like to express an opinion, 6705. Effect on diseased kidney thought of as small, 6707. No information on the point, 6708. No specific effect in pregnancy known, 6709-11.

Contra-indication of salicylic acid in cardiac affections, 6737, and perhaps in acute nephritis, 6738. Probably dangerous in acute forms only of kidney disease, 6739.

Harmful results of continued use of borax or boracic acid read of, 6702. No bad effects noticed when borax used for short period for epilepsy, 6703. It was mixed with bromide; not known which did the good, 6704. Might be dangerous to children to take 30 grains daily in milk, 6715-16. Would not like to administer 80 grains of boracic acid in a pint of milk, but could not say it would produce ill results on gastric cells, 6753-54. Leibreich's experiments known as to borax, boracic acid, and formalin, 6755, showing surprisingly little local effect on lower animals, 6756, adult dogs chiefly, 6757, and inference on puppies cannot be inferred therefrom, 6758.

Preservatives not thought of as likely to veil decomposition in milk, 6717-18. Preservatives are of use in the interests of public health, 6719, 6768. Less harmful than sour milk, 6720-21, or bad food, 6749-50, especially milk, 6751-52. Indiscriminate use should be remedied, 6722, 6749. Standardising of preservatives desired, 6723. Moderate use of preservatives to be thought of as lessening risk of diarrhoea by bad milk, 6769. Diarrhoea not attributed to boracic acid in milk, 6770, rather to lack of sufficient preservative to keep milk from going bad, 6771. All diarrhoea in children not due to bad milk, 6772-73. Diarrhoea should be decreasing by use of preservatives, 6782. Not known if it be so, 6783.

Idiosyncrasy probably not of much account *quâ* preservatives, 6749-50.

Medical profession do not regard preservatives in food seriously, 6727, nor do the hospitals, 6728. Physician's practice not stultified by preservatised milk, 6729, unless boracic acid were both prescribed and also in the patient's milk, 6730, as also with salicylic acid, 6731. Medical profession affected in this sense, 6732-35. The uncontrolled use of preservatives would be a bad thing from medical men's point of view, 6736.

Milk ideally should be sterilised or pasteurised and unpreservatised, 6723, 6760. Sterilised milk has advantages for children, 6724-25. Pasteurisation would be of great good as a germicide, 6726. But borax or boracic acid, or both mixed in quantity

Précis.

Précis.

just sufficing to preserve milk would probably be harmless to the majority of people up to four or five pints daily, 6759. Storage of unpreservatised milk in the houses of the poor may lead to its going bad before consumption, 6761, 6763-66. Exceedingly difficult to get poorer class to properly house milk, 6762. Uncleanliness of dairies arising from use of preservatives should be met by inspection, 6767. Hospitals get milk from good companies, 6774, and some have analyses made from time to time, 6775. Details of milk contracts not known to hospital medical staff, 6776-79. There can be no objection to contracts, 6780, and reasonable to exclude preservatives in the contracts, 6781.

JONES, DR. J. HOWARD. (Digest of his evidence.)

Medical Officer of Health of Newport (Mon.) County Borough, 1367.

Butter can be shipped for long distances without the aid of preservatives, 1309, as from Australia and Denmark, 1315, 1339-41. Samples found to contain 0.71, 0.74, and 1.3 per cent. of boracic acid, 1309. Limits of use of boracic acid in butter not determined, 1310, 1312, 1385. Such percentage as that last named would probably result in proceedings being taken, 1311, as it did successfully at Pontypool, 1320. Percentage considered by bench to be injurious to health, 1321. It was over 90 grains per lb., 1322. Butter now consumed quickly, 1342-43, local butter within a week, 1344-46. Preservatives unnecessary, 1361. Has known rancid butter to contain a preservative, 1363-64, 1378-84. Newport butter supply is local, and Irish, and Danish, 1400.

Milk can be kept sweet long enough for distribution without preservatives, 1309. Newport's milk supply local, 1399. The presence of preservatives would be an occasion for proceedings, 1405, formalin being excepted on account of likelihood of losing the case, 1408-11.

Boracic acid objected to altogether in milk, and unknown to consumer in other articles of food, 1313. No experience of ill-effects, 1314, 1316. Case of alleged ill-effects in person of a delicate lady, 1317-19, 1323-27, 1349-60, 1386-90. Boracic acid poisoning produces diarrhoea and vomiting, 1332; low temperature, 1333-35; and may much resemble chronic ptomaine poisoning, 1336; boracic acid would retard commenced decomposition in milk, 1366-68, 1374-75; and might prevent it being detected, 1369; but would not mask decomposed milk, 1370-73; but 1 in 30 would wholly retard decomposition, 1376-77. Newport pork butchers used to use 4 ozs. of borax preservative to 40 lbs. of meat, 1395-97; preparation called Glacialine, 1398.

Preservatives a source of unnecessary danger in milk, especially to infants and invalids, and a direct encouragement to neglect of measures of cleanliness, 1309, 1362, 1365; prohibited in milk and in appreciable quantity in butter, creams, prepared meats, and other articles of food under pain of penalty, in Newport (Mon.), 1309; great reduction in sale of boracic acid followed, 1391, 1395; and other forms of preservatives grew in demand, 1392-94; "Schering's Formalin Solution" being widely advertised, 1393.

Putrefaction in food known to cause illness, 1328; symptoms unlike those of boracic acid poisoning, 1329-30; save when chronic ptomaine poisoning occurs, 1336.

Food sampling in Newport not large, 100 samples per annum, 1401-4, 1406.

Colouring matters not troubled about, 1407.

KAYE, DR. JAS. ROBERT. (Digest of his Evidence.)

M.D., D.P.H., Medical Officer of Health of West Riding of Yorkshire, Fellow of the Chemical Society, &c., 5432-36, 5464.

Preservatives in milk and butter recently and specially studied as regards West Riding, with a population of over one million persons, 5437-42, and investigation to be continued, 5496. No proceedings taken, 5443, by reason of appointment of present Committee, 5463. Preservatives increasingly in use and found in milk, meat, and tripe, 5444. A list of five preservatives and data concerning their use were handed in, 5455 (App. No. 30). All compounds of borax and boracic acid, or pure boracic acid, 5456-57. Preservatives recklessly used by dredgers; cow

carcasses known to be dredged all over, 5462. Preservatives fairly generally used throughout the country, but less among co-operative societies doing a quick trade, 5473. Use of preservatives known as general during past seven years, 542. Present knowledge of extent of use not very great, 5495, but hope held of further information resulting from prolonged inquiry, especially as to seasonal use, 5496-97.

Boracic acid as a preservative deleterious, 5502. Dangerous to take 54 grains, 5506. Presumptive evidence obtains as to prejudicial effects of the acid, 5513.

Mortality of infants in third quarter of the year put down in part to large use of preservatised milk during the hot months, 5466-72. Infantile diarrhoea mortality always excessive in third quarter, 5474-76, 5481, and preservatised milk thought of as a factor in preventing fall in such third quarter mortality, 5477-78, 5484, but some improvement to be looked for as regards towns purveying unpreservatised milk if thesis be true, 5485-88, but some cause operating prior to use of preservatives, 5482-83, and perhaps decomposed milk, 5484, 5492. Diarrhoea may be produced by changes in milk, resulting from contained preservatives, 5493-94. Tinned milks not regarded as a prime factor, 5535-37, but they play their part, 5538-42. Diarrhoea caused by borax administered as a drug to children, 5503-4. Dosage not known, 5505. Conditions surrounding child-life tend to diarrhoea, specially in the third quarter, 5543-46. Boracic acid a greater cause than tabes mesenterica, 5553-56. Diarrhoea mortality-curves of Continental cities vending unpreservatised milk tend to show lower infantile rate, 5557-58.

Infants and invalids should not be subjected to indiscriminate use of preservatives in food, 5509-12. Actual evidence of harm is not great; but there is such, and certainly presumptive evidence as to boracic acid, 5513.

Physiological experiments point to injurious effects of preservatives, 5514-15, especially as to formalin, 5516-17. Preservatives to be effective must injuriously affect human delicate digestive organs, 5518, 5547-52. Boracic acid as a drug, and as a preservative daily in use, very different, 5552.

Milk largely treated with boracic acid or formalin in summer but free in winter, 5444-46; the same true of preservatives generally, 5489. Vendors declare preservatives to be necessary, 5447. Preservatives unnecessary in dairy produce, 5448-50, 5519, and undesirable, 5451, and a cloak for dirt, 5519-20. Adulterated milk most preservatised, 5458, and poor most likely to get such milk, 5490. Has found 20 grains of boracic acid in a sample of milk, 5459-61; probably the result of repeated dosage, 5462. Stale milk sold by aid of preservatives, 5498-5501. Suckling declining in West Riding, 5527. Use of tinned milk increasing, 5528-30, and used all year round, 5533-34, but general absence of preservatives therefrom not known, though not held improbable, 5531-32.

Cooling of milk increasing in West Riding, 5521-23. All farms should have proper water supply, 5524-26.

Order as to Dairies, Cowsheds, &c., indifferently enforced, 5452. Preservatives abet evasion of regulations, 5453-54. Insanitary conditions affect milk, 5479-80.

Cleanliness at a discount by use of preservatives, 5454. Dirt cloaked thereby, 5519-20.

Refrigeration, sterilisation, and pasteurisation on different footing to preservatives in milk, 5499-5502. Recommends sterilisation of milk, 5559. Doubts its indigestibility, 5560. Growing in use in Ripon, 5561.

Butter preservatised with 0.77 per cent. of boracic acid. Adulterated butters most frequently preservatised, 5458. Daily dosage of boracic acid in butter not likely to be large, 5507-8.

KELLITT, MR. JOHN. (Digest of his evidence.)

Appears on behalf of the Grocers' Federation, a body of 13,000 members, 1-2.

Has found no opposition to the use of borax as a preservative, 7; does not know the difference between borax and boracic acid, 10, 25; borax used with bacon packed in boxes, and dusted on bacon to prevent fly-blow and absorb moisture, 11, 12, 23; borax thus used for last 20-25 years, 13-14; bacon thus treated in increasing quantity, in place of

very salty American bacon, 15, 29, 33-35. Bacon, formerly cured in America and packed in salt; salt could not be extracted even by steeping; complaints arose as to excessive saltiness; bacon now cured, and salt washed off, and borax dusted over it, 15; saltiness thus reduced and slimy condition obviated, 15, 73-74; bacon still cured with salt and saltpetre, 16. Borax does not cure, 17, 20; nor saturate the meat, and penetrates very slightly if at all, 17-18, 36-38; bacon of to-day better alike for dealer and consumer than ever before, 19. Irish and Danish cured bacon was formerly too salty, especially in the "pocket"; shoulders formerly nearly unsaleable; this now altered, 21, 65-67; people will not now eat salty meat, 29, 31.

Borax used in the form of boron, a preparation of a nature drier than borax, and a quicker absorbent of moisture, 24; boracic acid not a trade term, 25.

No other form of treatment of hams than by dusting and packing with borax known; some American hams are pickled, but nature of pickle not known, 26; no suspicion of any preservative thus being used, 26-28.

Prohibition of borax preparations in ham would be serious in the absence of other equally good preservatives, 30; people will not eat salty meat, 31; one result would be that the trade would try and cure bacon that would not keep in Ireland, 32.

Tainted bacon much less frequent since preservative used, and no market now for such meat, as formerly, 39; fly-blown bacon, which used to cause loss in summer, rarely seen now; fly-blow only seen where meat is moist, 41; tainted bacon once marketable and in demand, 52; tainted bacon is bacon not sweet, 53; and was obtainable at cheaper rate, 54; but was preferred even apart from price, 55.

American hams kept in boxes with borax from three to six weeks, 57, 59, 63; borax washed off only in retailers' hands, 58, 62, and a great deal of the meat then sold within a week, 60.

Borax put on hams in process of packing, 61.

Bacon cured before borax is used; bacon hung up and dried after borax washed off; boron used generally in summer on this hung bacon, 64.

Irish and Danish bacon sprinkled with borax only on the shoulder portion; sides do not need sprinkling owing to short voyage, 68-69; hams generally cured with the sides, 70; no preservative detected on Danish hams, and but little if any used, 69-72.

Irish bacon cured like Danish 20 to 30 years ago; but borax now used to prevent slimy condition of meat, 73-74. Danish method an improvement on Irish mode of curing, 75.

Butter heavily salted not now saleable. Salt in excess in butter just as injurious as borax; borax in excess would impart an unpleasant flavour to butter, 43.

Butter chiefly from Denmark, and secondary qualities from Ireland, 44; witness has never bought Colonial butter, 49.

Danish butter remarkably good, and keeps better than English butter, 45-47. Witness not aware that any preservatives are used in it, 45, 49.

Use of preservatives in butter not within knowledge of witness, 50.

Provisions now used generally in a fresh state, 56.

LONG, MR. JAMES. (Digest of his Evidence.)

Professor of Dairying, Member of the Central Chamber of Agriculture, which he represents, 4565-69.

Preservatives not needed for dairy traffic, 4571, 4677-78. Used promiscuously, and 56 grains per gallon known, 4579, and also  $\frac{1}{16}$ th of oz. per gallon, 4580-81.

Milk trade does not call for preservatives, 4570-74. Separators introduced in some parts of Devonshire, 4594. Milk repeatedly preservative, 4604-11, though this is denied, 4612. Milk sent to London by witness from Hampshire and Hertfordshire, 4611-13.

Keeping quality of milk depends on many phases of cleanliness, 4588.

Cooling of milk well enables it to be kept 24 to 36 hours in hottest weather, 4577, that is, cooled below 60° F., 4578. Milk kept at 60° F. for first 12 hours will keep 36 hours in all in hottest weather, 4582-84. Milk cooled from 55° to 60° F. kept 36 to 48 hours, being scalded in sultry weather, 4588-93. Imperfect cooling has led to return of milk to witness, 4611.

Cleanliness essential to the keeping of milk, 4578. Four ounces of slime taken by heavy milk drinker per annum, 4579, 4691-93. Dirt masked by preservatives, 4671, 4695, which put a premium on good dairying, 4677.

Pasteurisation of all milk effected by one large dealer, 4585-88.

Sterilisation practised by witness, 4594; on small scale, 4599, but in places on a very large scale, 4600; process described, 4595-98. Bottle cleansing is a trouble, 4601. Bottled milk used in Switzerland, 4602. Milk cannot be tampered with in transit, 4603, and delivery is less frequently needed, 4604. Cleansing of bottles more difficult than of cans, 4697-4701, unless daily service in question, 4702. Bottling of milk on a large scale need not raise the price, 4707-9.

Butter from Denmark unpreservatised fetches a higher price than preservative French butter, 4629-42, 4672-76. Slightly salted butter is "fresh" butter in the market, 4642. Moisture in Irish butter same as in good butter, 4644. Factory and creamery butter not discriminated, 4645-57. Using Danish methods, Ireland could turn out equally good butter. People do not want preservative butter, 4658. Tuberculosis has nothing to do with Danish dairying system, 4670-71. Preservative butter insipid, 4671.

Keeping power of well-made butter without preservatives keeps it for six weeks, 4642. Neither pasture nor manufacture held to render Irish butter inferior to Danish in keeping power, 4644. Danish butter is from milk practically sterilised, and then re-inoculated by flavour germs, tending to keep it sweet, 4667.

Flavour of Danish butter not lost by pasteurisation, but not so fine as English prime butter, 4668, and cannot be made so fine, 4669.

Inspection of farms made in Denmark, 4665-67.

Bacon in Ireland not preservative, 4658. Restriction on use of borax packing would hamper Transatlantic trade, 4659, unless cold chambers used, 4660.

Fruit preserved in bottles without any preservative, 4663, but colour goes off somewhat, 4664.

Boracic acid objected to in food, 4661-63.

Injurious effects of preservatives on digestion inferred, 4579. Salicylic acid held to arrest peptic digestion, and heavily boracised milk, 210 grains per gallon, to be injurious to a milk drinker, 4613, 4696. Illness alleged to be caused by preservative milk, 4615-26. Preservative drugs in food objected to, 4627. Good deal of injury by preservative food suspected, 4628.

Prohibition of preservatives in milk would not restrict supply, 4572. Prohibition of preservatives should be enforced as regards substances, the effect of which upon infants and invalids is not known, 4689. The effect should be determined prior to use, 4703-6.

Declaration of articles as preservative should be made, if preservatives allowed, 4689.

Restriction to one preservative material and to a limited quantity should be enforced on vendors, and use allowed only in three hot months of the year, 4689.

Colouring matter used in some cheeses, and in butter. Breed of cattle affects and effects colouring of butter. Annatto is harmless. Some colours, as aniline yellow and methyl orange, produce undesirable symptoms, 4684. Colouring should be prohibited in dairy produce, 4685, and but little hurt to trade would result, 4686. Colour in cheese merely a question of public fancy, 4687-88.

LOUGH, MR. ARTHUR S. (Digest of his Evidence.)

Member of the Irish Agricultural Organisation Society, and Managing Director of the Cavan Creameries, Limited, 6614-17.

Creamery industry revolutionised of late years in Ireland, 6618, and very largely increased, 6619-20. Nearly all the creameries use preservatives in summer, 6621. Only butter made, 6622. Farmer waits for the separated milk, 6623. for feeding calves, 6624. Cleanliness is observed at the creameries as to milkers, cattle, utensils, storage of milk, and so on, 6677. Straining is insisted on, 6680.

Factory butter not touched at creameries, 6642. A source of annoyance to creameries, and often sold as creamery butter, 6643. It is not creamery butter, 6644. It is different from, 6645, and inferior to

Pécis.

creamery butter, 6646. Irish and Normandy factory butters of very different class, greatly in favour of the latter, 6647.

Preservatives not essential to creamery industry. They are asked for, but less quantity than used would suffice. No complaints made of use of preservatives, 6625. Preservatives needed because butter required to keep. If used fresh, need for preservatives would be less, 6626. Preservatives should not be requisite for butter from field-drawn milk, 6629. Conditions of housing of cattle in Ireland more favourable to prohibition of preservatives than in Denmark, 6656-58. Use of preservatives deprecated in agricultural products, 6659. They would be quite unnecessary in a few years in creameries, with proper organisation, 6660. Presumably preservatives in butter would be harmful, 6668. They should be done away with, and are being got rid of in witness's creameries, 6676. Borax chiefly used, 6681.

Restriction rather than declaration of preservatives advocated, pending prohibition, 6662; latter might handicap the trade, 6662-63. Would like to know if he were taking a harmful preservative, 6669-72. Consumer has a right to know, 6673-75, but not as to butter only, 6675.

Prohibition of preservatives would be a hardship on some butter-makers for a long time, 6661, 6683-84. Harmful preservatives should not be used, 6664-67.

Pasteurisation more needed in winter in North than in South Ireland, because of the winter stall feeding of cattle, 6627. Denmark needs pasteurisation for same reason, 6627-28, and to erase feed taint, but butter from field-drawn milk needs no pasteurising, 6629-30. Pasteurisation held to be most valuable, 6631-32. Temperature in pasteurising some 175° to 185° F., 6633. Improvement of milk of house-fed cattle by ferments or cultures not known, 6634-36. Practical difficulties in dealing with large quantities of milk are being overcome, 6690.

Keeping power of butter greater when both pasteurised and preserved, 6682. Salt must be used if butter be kept some time, 6685-86.

Cream has been sold without any preservative, 6688-89.

Transit of butter in Ireland the curse of the trade, 6637, 6639. Redress hoped for at the hand of the new Agricultural Board, 6638. No traders' rolling stock in Ireland, 6640. Procedure for compensation very unsatisfactory, 6641. Matters in Ireland worse than in Denmark, 6687.

Cattle housed in Denmark eight or nine months a year, 6654-56, in Ireland from four to six months, 6657.

Water supply to farms not looked to, 6678, but supply is good in North Ireland, 6679.

Colouring matter hardly ever used in creameries, 6648. Some dairies use annatto in very small quantities, 6649. Winter butter nearly same colour as summer butter, 6649-50, 6652, with mixed breeds of cattle, 6651; no Channel Islands cattle in question, 6652. An error in scalding may render annatto necessary, 6652. No great difficulty as to colour, 6653.

LOVELL, MR. JOHN CARY. (Digest of his Evidence.)

(Appears on behalf of the Butter Association.)

Butter trade, experience of, since 1852, 706; in a large way, 707. Trade has greatly developed of late, 708, 710; preservatives have conduced to this, 709, 711; fresh and unsalted butter now demanded, 710. Nearly all butter now treated with preservatives, 716. Dry butters keep best, 769. Continental butter on consumers' tables three days after manufacture, 793-95. If it keep a week the purpose of trade will be served, 796-99, 805. But it must be kept in a cool place, 800. Butter cannot be treated so as to keep more than a week, 804.

American butter was spoiled in transit prior to use of preservatives, 712.

Normandy salted butter, only, imported 40 years back, 713. Goes into consumption at once on arrival, 801-2. Is on consumers' tables three days after manufacture, 725, 793-95. As now imported it keeps better than Danish butter, 726. A finer article than Danish, 730. It contains one half per cent. of preservative, 762-63.

Irish butter of relatively weak quality, 737, on account of food, 738, 772, and wet weather, 739-40, and pastures, 772. It now comes fresh, and has greatly

improved, 741-44. Some made still on old modes, but preservatives enable it also to be successfully placed on the market, 747. Made principally in small quantities, hence cannot successfully compete with Danish trade, 750. Danish methods would not help without preservatives, 766. Has much more moisture than Danish butter, 767, affecting its keeping quality, 768-69. Could not be got as dry as Danish butter; has an average of 13½ to 15 per cent. of water, 770.

Belgian butter will not keep well, 766.

Danish butter treated with preservatives; fresh butter not imported from Denmark, 717, 771; preservatives not used at first; the butter does not keep like Normandy butter, 718. A great deal of it pasteurised, 727; butter not so fine in consequence, 729. Danish butter superseded on this account, 730. Made on a scientific basis and in bulk, hence competes successfully with Irish trade, 750-51. One half per cent. of preservative insisted on where possible, 752-53. Danish butter very solid, 773.

Argentine refrigerated butter almost waterless, commands high price, and keeps well, 773. Contains not quite half per cent. of preservatives, 774.

New Zealand butter with ¼ per cent. of preservative retains full flavour in cold store for nine months, 727. A finer winter article than Danish, 730. Without preservative one-half would spoil, 776, by reason of process preceding refrigeration, and liability to spoil after it has left cold store, 778-81. It is cold stored on arrival, 802.

Scandinavian butter sometimes contains preservatives, 752-54. No Swedish or Norwegian law known against such use, 755-56, 758. Very little Norwegian butter exported yet, 756-57. More comes from Finland, 757.

Margarine preserved with borax and boracic acid, 806.

Preservatives have largely superseded salt, 714. Borax and boracic acid only used, 715; these, and these alone answer all purposes. Tasteless in small quantity, 806. Only minimum requisite amounts used, 718, 737. Only used as an essential, 749. One-half per cent. impressed on consignors, 719, 720. It is regarded as the necessary minimum, 790-92. It suffices to keep butter three or four days, 725, 783, 793. Necessary to Irish butter trade, 737, 747. Brazilian Government objected to preservatives in tinned butter in 1891, 720. Legislative prohibition of undue use of preservatives advocated, 722, 724. Large amounts kill bad flavour and partial decomposition of butter; over 1 per cent. detectable, 723, 783-89. Has found 2½ per cent. in butter, 787. Butters repeatedly analysed as to quantity of preservative used, 775. Preservatives used for all imported butters, 782. Will only keep butters a week at most, 803-4. In solution on wrappers will not suffice to keep butter, 807; used thus simply to prevent injury to butter from wrapper dressing, 808. Personal and family use of boracised butter, and milk, large and continuous, 809-15.

Prohibition of preservatives would stop Irish butter trade, 737, 765, and injure the butter trade generally, 764.

Pasteurisation of butter destroys its fine flavour, and the keeping qualities of frozen butter, 727. Given up by Colonies and the Argentine, 728. A fad of the Danes and very expensive, 730-31. Milk raised to 170 deg. F. and then separated, destroying fine flavour of cream, 732-33.

Formalin held to be injurious, 806.

Weather affects the texture of butter, 739, 772, and its keeping quality, 740.

Colouring of butter and cheese needed only to satisfy the varying local public demands, 734-37.

LOWE, MR. W. F.

Public Analyst for Chester City, Carnarvonshire, &c., 3295. Witness deaf, 3297.

Has prepared a memorandum stating his views on use of preservatives in food, 3296, which he handed in, 3297. (Appendix No. 16).

MCCRACKEN, MR. ROBERT. (Digest of his Evidence.)

Managing Director of Dunragit United Creameries 2849-51.

Preservatives long used at Dunragit Creameries, 2852, in milk, cream, and margarine, 2853, but not in butter, 2854.

Boracic compounds used as preservatives, 2856, borax and boracic acid and compounds, used, 3007-9.

Milk preservative added to a little milk and then mixed with bulk, 2862, and intimately distributed, 2863, but only in summer, and  $\frac{1}{2}$  to 1 oz. to 16 gallons, 2878-79. Milk could not be carried to a distance without a preservative, 2869. Cooling milk will aid its keeping quality, but not long in hot weather, 2870-71. Milk formerly not sent long distances. Some now comes to London from Scotland, 2872, and is delivered a day old, 2873, and then goes to consumer, 2874. From 10,000 to 15,000 gallons of milk per diem reach the Dunragit Creameries from four to five thousand cows, 2875. Milk not preservatives by farmers, 2876, 2925, under a stipulation, 2877, 2926, but milk not tested, 2927. No complaints of preservatives milk, 2880, and no proceedings taken against the Creameries, 2881. Milk not sterilised, 2894. Does not like it; has pasteurised some, 2895-96, but only experimentally, 2899, it flavours the milk, 2900, objectionably, 2901. Milk raised to 160° or 170° F., 2902. Cost not known. Only skim milk sent out, all pasteurised, 2903-5; skim milk changes just as quickly as new milk, 2906. Price of skim milk would not pay for sterilising, 2907. Price has not affected question of sterilisation, 2908. Skim milk goes into the cities, 2909, as separated milk in winter; in summer it is made into cheese, 2910. Carriage to London spoils the skim milk, 2911, by reason of cost, 2912. Havant Dairy Factory not known, 2913-17. Continental milk trade not known, 2918-19, 2921. Circumstances may differ from Scotland, 2920. Aylesbury Dairy Company's procedure not known, 2922. Refrigeration assists keeping quality of milk, 2923. Many farms have no water supply for cooling milk, such as would render use of preservatives less needful, 2924. Preservatives need not exceed 30 grains or so per gallon, 2928. Milk sent out daily; some may at times be 24 to 28 hours old on despatch, 2933-36. Preservative added systematically to each can as ready to go out, 2937.

Cream preservative added mixed in a little milk and well stirred in, 2864, 2868. Some cream sent in jars, some in bulk, 2865, in differing quantities, 2866, all preservatives, 2867. Cream would not keep well without a preservative, 2869.

Butter sent out fresh, saltless, 2854, and consumed quickly, 2855. Butter intended to keep must be preservatives, 2858. Danish butter contains a little salt, 2859-60, it is called "fresh" in England. "Fresh" butter in Scotland is quite saltless and unpreservatives, 2861. Scottish butter used day by day. Irish butter does not keep very well, 2938-39, it is occasionally used, 2940. Demand irregular, 2941-43. Western Ireland butter takes three days to get on Scotch market, 2942. To London an extra day would be taken up, 2944-45. Butter carefully made and quickly consumed needs no preservative, 2946. Great variety in factory and creamery butter, 2947, due to handling and manufacture and method of supply of milk, 2948. Defective water-supply also a factor, 2950. Percentage of water in good Scotch butter unknown, 2994. Less than Irish butter, 2995, dry as Danish butter, 2996. "Mixtures" not made at Dunragit, 2997.

Salty butter in less favour than formerly, 2857. Butter must now be absolutely fresh, 2951. Danish butter with 1 per cent. of salt does not compete with "fresh" butter, 2952-53.

Pasture does not affect keeping quality of butter, 2949.

Margarine trade of to-day necessitates use of preservatives, 2857. Keeping quality not known to be inferior to butter, 2858. Preservatives keep margarine longer, 2882, 2884. A month or six weeks, 2991, and longer than fresh butter, 2992, as long as salt butter, 2993. Salt also added; absolutely fresh margarine not known to be consumed, 2883. Contained milk makes the margarine "go off," 2885-86. Added to flavour it, 2888-90. Dutch method of milkless manufacture without preservatives not known, 2891-93. Preservatives needed about  $\frac{1}{2}$  per cent, 2929. No objection would be taken thereto, 2930.

Formaldehyde in milk used in a few samples, 2932.

Declaration of preservatives should be made if proved to be injurious, 3005-6.

Colouring universal in dairy products, 2954, but not in great variety, 2955. Chiefly annatto, 2956-57. Aniline colours no doubt used, 2958-59. Nature unknown, 2976-77, 2981-82, 2985-90, 3000-1. Yellows

used in harmless quantities, 2978, from the Continent, 2979, from Germany or Holland, 2998-99; a Dutch maker vends them, 2999, names not known, 2980. Aniline and annatto mixed, used, 2983, but constituents not known, 2984. Uniformity of colour desired, 2960. Prohibition would close some markets to Scotland for cheeses, 2961. Others will not take coloured cheeses, 2962. Margarine coloured for like reasons, 2963-64, and to resemble butter, 2965. Declaration of colour would make no difference, 2966-67, 2970, only harass the trader, 3004, but all trades should be treated in same way, 2968, 2971-72. Everybody knows cheeses are coloured, 2969. Poisonous colours should be declared, 2973-74. People would avoid knowingly eating coppered peas, 2975. Martius' yellow unknown, 3002-3.

Restriction needed of quantity of preservatives to be used, 2931.

Précis.

McFADYEAN, PROF. J. (Digest of his evidence.)

Principal and Dean of the Royal Veterinary College 1751.

Milk should contain no preservative; it is unnecessary undesirable, and, as a rule, physiologically indefensible. If used in useful quantity, a preservative might be distinctly injurious, 1752. Children on milk diet would suffer. Pure milk contains no germs essential to fermentation. Preservatives predispose to lack of sanitary precautions, and of care to eliminate dirt from milk, 1753. No knowledge of extent or quantity of preservatives used, 1754; himself gets the best milk available, 1755. Milk is a good ground for bacterial growth, 1761. Boracic acid would lose its germ restraining effect if the preservatives milk were diluted, 1772. Prohibition of boracic acid in milk would not raise its price, 1773; nor render it more difficult to attain fresh appearance and taste of milk. If milk and butter brought a better price, more land would revert to dairying purposes, 1774.

Butter should only, for physiological reasons, have salt added as a preservative; other preservatives unnecessary, 1756, 1758; though all samples will go wrong without them, 1762. Volatile agents would not be inhibited by preservatives, 1757; which are physiologically indefensible, 1758. Heavily-salted butter not now pleasing to the public taste, 1760. Irish creameries may not be so clean as in Denmark, and thus affect the keeping quality of butter, 1762-63. Butter to keep some two or three months would meet trade requirements, 1788-89.

Declaration simply of butter as preservatives would not suffice, 1759.

Preservatives, apart from salt, objectionable and foreign to the body, 1756, 1778-81. Boracic acid held to be detrimental to health, 1764-65. No specific case known, 1766. Boracic acid does not remove signs of putrefaction, 1767. No physiological manifestations in an adult would follow a dose of 30 grains, 1768, but if continued daily for months such doses could not fail to have effect, 1770. Long experimentation would determine the results of the effects produced, 1796-97. Non-observed results might none the less be injurious, 1798-99. A child might take an enormous dose in its milk, 1769. Form of excretion of the acid not known, 1771. It is a feeble germicide, but restrains the growth of germs, 1772. Its injurious qualities inferentially presumed, 1775. Not known to be non-injurious, 1802, and hence objectionable, 1815-16. A preservative to be of use must be of a strength to restrain bacterial growth, 1782, and might then be distinctly injurious, 1752. Time not a factor in its use, 1783-86, though time is an important trade factor, 1787. Formalin strongly objected to, 1792-95, 1806, as opposed to life, 1807, 1810. Boron in boracic acid is what is objected to, 1804. Poisonous substances might not affect higher and lower forms of life in the same degree 1808, but the exceptions are rare, 1809.

Salt is a food, and enters into the composition of the human body, 1776; is a feeble preservative, less so than boracic acid, 1777.

Sugar defensible in fruits, 1776.

Pasture does not affect butter, 1761; food might affect its texture, but not its keeping quality, 1762.

Pepper not foreign to the animal body, 1800.

Strychnine not to be used as a preservative, 1801, because known to be injurious, 1802.

Précis.

**MANN, DR. JOHN DIXON** (Digest of his Evidence.)

Professor of Forensic Medicine and Toxicology, Hospital Physician, &amp;c., 2601-2.

Preservatives: some undoubtedly injurious in themselves, 2604, salicylic acid being one; some probably injurious, 2604; some retard or prevent digestion; and as added to foods preservatives do not sterilise food, 2605. Experiments as to injurious results of preservatives in foods must, to be conclusive, be long continued, as in the case of water-borne lead poisoning, 2611. Preservatives inhibit the action of enzymes, 2617-19.

Boric acid injurious in cases of external and internal use; cases quoted, 2607. More frequently used in milk than formaldehyde, 2608-10. Not to be compared with salt as a preservative, salt being a natural constituent of the human body, 2628.

Formalin as used in foods retards digestion, 2607. Experiments show the arrestive action of formaldehyde on pancreatic ferments, 2619. Formaldehyde not justifiable in food, 2626, but in foods only occasionally used, may possibly be harmless, 2627. It is a blood poison in large doses, 2629. Its poisonous effects in proportion to antiseptic efficacy not known, 2630-32.

Salicylic acid in cider persistently consumed found to cause internal disturbance, 2611.

Prohibition of boric acid in milk should be absolute, 2606, as should all preservatives, 2627-28.

Diarrhoea in infants thought of in relation with boracised milk 2605-7, 2628.

Milk kept sweet by boric acid as ordinarily used for a limited period only; injurious products in boracised milk may be formed, 2605, 2612. Micro-organisms found to have multiplied in boracised milk, 2613-16.

Coppered peas should be prohibited. Copper not a constituent of the body. It produces chronic poisoning, 2621. Occasional doses of coppered peas could not be proved harmful; but the more potent as a preservative copper becomes the more harmful also, 2622.

Colouring matters apart from copper not studied, 2623-25.

**POORE, DR. G. VIVIAN, M.D.** (Digest of his Evidence.)

F.R.C.P., M.R.C.S., 7336, Physician to University College Hospital, 7337, Professor of Medical Jurisprudence and Clinical Medicine at the University College, London, 7338.

Prohibition of preservatives advocated unless declaration of nature and amount be made, 7339-40.

Preservatives in certain cases harmful, and want of fresh food harmful to health of community, 7340. Scurvy follows prolonged use of preserved food, 7341, 7414-17. Food chemically preserved might be positively harmful, 7342, but ignorance at present obtains as to the action of chemical preservatives, 7341, 7349. No reason why chemical treatment of food should not be innocuous, 7421-22. Preserved vegetables have failed to prevent scurvy, 7343. Scurvy decreasing by reason of added precautions, 7344. Even preservative lime juice has failed as an anti-scorbutic, 7345. Fresh food most important, 7346-47, and productive of energy, as instanced by animal life, 7350-60, and preservative food different from fresh food, 7348-49. There should be no confusion between fresh and preserved foods; even frozen meat loses its flavour, and a great deal becomes flabby and unappetising, 7361. Salt meat speaks for itself, 7362, whilst preservative and preserved foods do not, 7363. People should be able to get fresh food, 7373, and should use it in due proportion, 7376. It should be produced near centres of population, 7418. Preserved food inevitable, 7374, and demanding its place in dietaries. Best mode of preservation should therefore be adopted, 7375. Fresh and preserved foods should be differentiated, 7391-93. Preservatives may deceive on this point, 7412-13.

Nutrition much to do with susceptibility to fatal disease, 7394-97.

Milk preservative soon ceases to be fresh milk, 7349. Advantage gained if milk kept from going putrid, 7364, or if germ growth be inhibited; but milk treated for the consumer is not like the milk as drawn from the udder, 7365, 7420. A great thing to give people wholesome milk, 7420. Modern conditions among the poor for keeping milk very bad, 7419.

Sterilised milk cannot be regarded as the same thing

as fresh milk, 7366. What happens to pasteurised milk kept under modern low-class filthy town conditions is matter of serious conjecture, 7419.

Declaration should be made of pasteurisation equally with preservative, 7367. All preservatives should be declared, 7377-79, 7381-82, 7386-89, 7391, and the amount of salt, 7380. No difficulty felt as to labelling, 7390.

Fraud goes on as to so-called "smoked" food, 7383-85. "Smoked herrings" painted with pyroligneous acid, 7385.

Colouring matters should not be used; such use is provocative of danger; they should be declared in butter, 7368. Uniformity of colour means artificial colouration, 7369. All aniline dyes should be declared, 7398-99.

Copper in peas indefensible, 7370, in any quantity, 7371-72, 7403-4. Held to be soluble in the human body, 7400-2. Fraudulent in peas, 7405; its usefulness not admitted, 7406. When used it should be specifically declared, 7407-11.

**PROSSOR, MR. JOSEPH EDWARD.** (Digest of his Evidence.)

Has had a long experience of provision trade, 556-58, and as a bacon curer, 564.

Heavily salted goods not now saleable, 559-60. Much salt would be needed if preservatives were not used, 570.

American and Canadian hams packed in dusted borax, 594, and borax washed off after arrival, 597; home hams smoked as a rule, 595.

Boric acid and borax mixture used as a preservative, 561-62, for dusting over mild-cured meat, 563, and used during the salting of the meat, and afterwards washed off, 566, 569, and at times in hot weather used as a solution to prevent fly-blow, 567, and this again washed off. It would remove all slime, 598, 607-9. Generally 4 ozs. per 100 lbs. of meat used, sometimes 1 lb. used, 569, 588-89, a good deal of this washed off, 590-91. It has some penetrative effect, 592-93. Kept on meat till cure complete, seven to ten days, 582-87.

Experiments made personally with continued doses of preservative without ill effect, 571, 574-81, 602-6.

Preservative largely used in household, 599 even for children's food, 600, without ill effect, 601.

Gave expert evidence for defendant in proceedings as to boracised ham at Pontypridd, 571-72.

**RADCLIFFE-COOKE, MR. CHARLES WALWYN.** (Digest of his Evidence.)

Member of Parliament, and cider and perry maker, 6574-75, 6590.

Cider and perry need no preservative; none used by witness, but sulphur burned in vessels, 6576, 6604, and vessels kept clean, 6605-6, and skim milk used for thickening purposes, 6576. Sulphur fumigation destroys germs and slightly retards fermentation, 6577, 6609-10. No objection to sulphur sterilisation of vessels, 6606. Many makers use preservatives, 6578, nearly all being preparations of borax or salicylic acid, 6579, which are put in at any stage of manufacture, to stop fermentation, sugar of boron being one kind, used also in mineral waters and non-alcoholic beverages, 6580. Sugar of boron used also in brewing; "Cynin" also used in cider; it consists of a solution of salicylic acid and borax in glycerine; experiment showed it an excellent preservative, 6581, but the cider kept by its use was not matured, and the control unpreserved cider had been lying about unheeded. Another cider preservative, "Walter Gregory's Powder," consists of salicylic acid and a small quantity of red oxide of iron, 6582. Formalin seldom used in cider. "K.M.S." not analysed. Anti-ferments are used to make bad cider good. "Hawkes' Anti-ferment" of a different class. Formalin used for brewing and mineral waters. "Hawkes' Cider Restorer" used for decomposed, ropy, and unhealthy cider, 6585. Cider not often fortified, 6587-88. Preservatives known of from advertisements are from Somerset and Devon, 6589; advertisements handed in, 6603. Nothing known of the use of preservatives in French cider, 6591-92. Preservatives are substitutes for cleanliness and induce carelessness, 6593. Public probably know of their use, 6594. Certain firms advertise no chemicals as used, 6595, 6599-6601, and then use them, 6596-97. Declaration of preservatives should be made by label on the

bottles or vessels, 6598-99. Would not use boracic acid or formalin, 6607. They stop fermentation, cider never reaches maturity, and they are harmful, 6608. If preservatives permitted, no reason why present non-users should use them, 6611-12; and prohibition would affect only the dishonest trader, 6613.

**RICHMOND, MR. HENRY DROOP.** (Digest of his Evidence.)

Analyst to the Aylesbury Dairy Co., 5639-40, 5726-27.

Preservatives not used by Aylesbury Dairy Co., 5641, save in some imported butter sold by them, 5642. Preservatives in general use principally boric compounds, 5643. Analysis handed in, 5644-45. Salicylic acid, soda, and magnesia in a glycerine solution also in question in two samples of preservatives, 5645. Formaldehyde also used, 5647. Difference between boracic acid, formic aldehyde, and salicylic acid in dilute solution one of degree, but in strong solution, one of kind, 5747. Fluorides not found, 5749. Hydrofluoric acid in large quantity found experimentally to be the most perfect preservative for milk; and fluoboric acid extremely strong preservative, 5750. Data promised, 5751-52.

Boracic acid as a commercial preservative contains on an average 56.8 per cent. of boric anhydride, 5676-77. Not a germicide, 5742, rather an anti-septic, 5743.

Salicylic acid stops the action of certain enzymes, 5745-46.

Formaldehyde used, 5647, believed largely, 5649, sold to trade in 1, and used also in 40, per cent. solutions, 5648. May be thought of as rendering milk less digestible, 5652-58. It kills micro-organisms, 5742, in relatively strong solutions, 5748, and is a disinfectant, 5744.

Analysis qualitatively of preservatives easy, 5702. Also quantitatively as to boracic acid and salicylic acid, but not formaldehyde, 5703-5, a volatile substance, 5706-10, and difficulty as to precise quantity originally present arises, 5711, and the strength of solution employed, 5712-14. Question of cost comes in as regards quantitative analyses, 5741.

Restriction of quantity of preservatives by limitation inoperative, 5753-54.

Prohibition of preservatives or nothing advocated, for several reasons, including liability to repeated dosage, 5754.

Milk vendors use formalin and boracic acid equally, 5650.

Keeping quality of preservative milk matter of experiment, 5714-15 (App. No. 31). Trade purposes of Aylesbury Dairy Co. served by ability of milk to keep 18 hours, 5729, and should be so for all trade purposes, 5730-31. No need for preservatives to secure this, 5732. At 70° F. milk keeps sweet for 34 hours, for 22 hours at 80° F.; for 15 hours at 90° F., bottled, in a chamber, 5732-33. Highest temperature of milk on first reaching Aylesbury Dairy Co.'s premises, 77° F.; highest on coming back from a round, 85° F., 5733. Some few complaints of sour milk, 5734-35. (*See Mr. Hattersley's evidence.*)

Cream preservative by formalin, borax-boracic acid, and saccharated lime (called "viscogen") which retards curdling and evidence of sourness, and is an alkali, 5659-64. "Special Cream Compound" used, a borax-boracic acid-saccharin mixture, 5664-66. Aylesbury Dairy Co. used to use 0.2 per cent. of boracic acid in cream, 5667; not now, 5668; it was objected to, and found to be unnecessary, 5669. No preservative used now at all, 5670-72.

Butter preservative by Aylesbury Dairy Co. years ago, 5673, but not now, 5674, 5679. Butter was either washed with a solution or had the acid worked in, 5675. By washing, some of the acid was retained in the butter, 5676, boracic acid itself being used, 5677, and  $\frac{1}{2}$  per cent. added, 5678. Done away with because objected to by the public, 5680-81, and as matter of policy, 5682. No consequential trouble, 5683. Butters imported from France are preservative, 5684. Percentage of boric anhydride contained handed in, 5685-86. Still sell such butters, 5687. Boric compounds not absolutely necessary in such butters, but trouble may be caused by non-use, 5688. Salt equally efficacious, 5689. Danish butters found free from preservatives, 5691. Up to 1899 Australian butters found

to be invariably preservative, 5692-93; when two good saleable butters were found free, 5694-96, 5736-37, 5740, but with salt, 5738, some 2 or 3 per cent., 5739, and no absolute necessity for preservatives inferred therefrom, 5697. Quantity in such butters reduced of late, 5698, from 1 to  $\frac{1}{2}$  per cent., 5699, without known change of mode of transit, 5700-1.

Keeping butter leads to decomposition in three ways, 5716-18; dry butters tend to keep better than moist, 5719-24, but the action of water can be counteracted by salt, 5725. Trade purposes of Aylesbury Dairy Co. served by ability of butter to keep one week, 5728. Action of preservatives on butter chiefly chemical or chemico-biological, 5755-58.

Colouring matter used by Aylesbury Dairy Co., annatto only; its nature and constitution described, 5759. Aniline colours also being used in the trade, 5760, in extremely small amount, 5763, about 100000. 5764. Colouring of butter should be standardised, 5762. Picric acid derivatives never found, 5765. Artificial colour in milk does not rise in the cream, but remains in the skim milk, 5862-63. Complaints have been made of uncoloured milk being poor, &c., when milk was excellent chemically, 5870-71.

**RIDEAL, DR. SAMUEL.** (Digest of his Evidence.)

Doctor of Science and Fellow of the Institute of Chemistry, 3679.

Toxic properties of boracic acid studied experimentally, 3680. Dover case of alleged boracic acid poisoning not accredited, 3778-80.

Milk can be kept for 24 hours even in warm weather by formaldehyde  $\frac{1}{50000}$ , or a mixture of borax and boracic acid about  $\frac{1}{3000}$ , 3681. Preservatives should be added at time of milking, and then  $\frac{1}{75000}$  of formaldehyde would suffice, 3697. Acidity of milk and organic growth rapidly take place, 3698. No known difficulty in adding preservative immediately after milking, 3699. It is done by some, and might be done by all, 3700. Milk containing a preservative can be kept sweet over night, 3762-64. It is probably 24 hours old in the morning, 3765-71. Admixture of preservative should not be left to consumer, 3777.

Invalids or very young children should not take unpreservative milk, 3694.

Restriction of amount and also declaration of preservative in milk should be made, 3693.

Digestibility of food inappreciably affected by  $\frac{1}{50000}$  of formaldehyde or  $\frac{1}{7500}$  of borax and boracic acid mixture, 3681-82; only slight retardation takes place, as shown by experiments, 3683; experiments made of comparative effect on digestion of one and another article of food and drink, 3684. Circulation and cumulative properties of articles consumed have their effect on the system, 3685-86. Digestive mixture filtered, 3772-76. Higher proportions might be taken; the question one of idiosyncrasy, 3691. The amounts in question can be safely taken by the majority of persons if declared, 3694-95; they would suffice for trade purposes, 3696.

Rash known to be produced in cases by 20 grains of boracic acid, and an individual living on a milk diet might consume very nearly this much, 3692. Health aspects of large amounts of preservatives not studied, 3781-82.

Experiments on animals show that feeding of animals with formaldehysed food has no effect on the nutrition of cats, guinea-pigs, or rabbits, 3687; young cats difficult to feed successfully. Some kittens fed on formaldehysed milk,  $\frac{1}{50000}$ , and boracised milk,  $\frac{1}{2500}$ , and taking 70 c.c. of milk per diem, increased in weight; in later experiments cats of three months, and adult guinea-pigs and rabbits used, 3688-89. One animal fed first on formaldehysed and then on boracised milk also gained considerably in weight, 3689-90. No preservative needed for milk kept 39 hours at 55 $\frac{1}{2}$  deg. Fahr., 3701-18; nor for milk kept 23 hours at 64 deg. Fahr., 3719-26; and preservative shows little preservative effect on milk even at the temperature of a summer's day, 3727; but there is just sufficient retardation of acidity of milk to justify the use of the preservative, in view of witness's opinion on the point of acidity of milk at which it curdles, viz. 0.25 per cent., 3728-57, and the preservative should be added before any appreciable acidity has started, 3758. The milks used for experiment were some three hours old, 3759-61.

Precis.

**RILEY, MR. JAMES. (Digest of his evidence.)**

Represents the Liverpool Chamber of Commerce, 816. Butter importer, 818; especially Danish, 819. Trade purposes would be served if butter kept a month, 849. Condition as to keeping quality known only to depend on preservatives, 850, but imperfect make tells against keeping power, 851. Examination of butter would not enable its keeping quality to be determined, 852; nor would its texture affect it, 853-54.

Danish butter keeps as well as any, 819; salted to taste, but keeps with or without salt, 833; holds its own and commands good price on the Midland and Northern markets, 843-44.

Irish secondary butter is factory made, with salt and preservatives, 820.

Canadian butter sent without preservatives, 819, 839; it is pasteurised, 820.

Normandy butter entirely a South England commodity, 827.

Australasian butter imported, Australian with, New Zealand without, preservatives, 828-29, 832; presumably, 834-35, 837-38; latter comes in cold chambers, 830; fresh, 831; with some salt, 832; keeps sweet three weeks out of cold chambers, 846, in winter certainly, 847, when alone it comes, 848.

Preservatives unnecessary with well-made butter, 819, 836-37; extensively used in Irish butter, 820; not used in some creamery butters, 821-22.

Prohibition of preservatives in Canada, 819. This would kill the Irish butter trade, 820.

Pasteurisation accounts for good keeping quality of Danish butter, 819. To be commended, 823, 840; it improves butter, 824-26, 841. Danes have employed it some years, 842.

**ROBINSON, DR. M. KENT. (Digest of his Evidence.)**

Medical Officer of Health for East Kent Combined Sanitary Districts, &c., 3298-99.

Preservatives in food studied, 3300. Often in milk, though not found by analysts, 3307. Dover milk largely free from preservatives, 3308. Broadstairs milk said to be preservative, 3309. Preservatives conceal dirt, putrefaction, and infective quality of milk, 3312. Should not be allowed in milk, 3335; not even if declared, 3336, and limited in amount, 3337-38. May be taken in many articles of diet in a day, 3336.

Milk treated with boracic acid by a dairyman, and also with "glacialine" containing as its basis boracic acid, by the cook, held to have led to serious illness of five of seven inmates of a house, the two who had not participated in the milk escaping. Milk taken alone, blended with tea, or in blancmange. Symptoms were vomiting, colic, suppression of urine, and great prostration. Of nine fowls which took the blancmange five pullets, which ate voraciously, died, 3301, 3345. Amount of milk taken by sufferers not known, 3342-43, 3346-47. The two inmates who escaped had a little milk in tea or coffee, 3314-16. Crop and gizzard of fowl and the milk examined. Blancmange not examined. Boracic acid held to have caused the illness, 3302. Quantitative analysis of milk not made, 3303, 3305. Boracic acid in large quantity found deep seated in fowl, 3303, 3344. Symptoms such as would be expected from borax or boracic acid, 3304. All possible factors other than boracic acid eliminated as cause of illness, 3305, in the house in Dover, 3306. Blancmange deemed the cause of the illness, 3313. Milk and blancmange both implicated, 3317; latter made of ground rice, eggs, sugar, boiled milk, and vanilla flavouring, 3318-19, and the contained milk held to be special factor, 3320, but some other constituents may have been in question, 3321. Farm furnishing the milk visited, 3322. Boracic acid added to the milk by the milkman, 3323-26, this and the added glacialine doing the harm, 3327. The milk would be consumed in other houses, but not known to have had glacialine also, 3328, and in this respect would differ, 3329, possibly, 3330-31. Quite possible that cases of infantile diarrhoea and enteritis in the town may have had relation with the particular milk supply, 3332-33. Possibility of preservative milk having relation with infantile diarrhoea almost a conviction, 3334.

Boracic acid should not be added to milk, 3305, even

if limited in amount, 3336-37. In 1 in 1,000 a baby might get an overdose in a day, 3338.

Experiments by large dosage of individuals with boracic acid not of much worth by reason of idiosyncrasy, 3339. Salicylic acid suits witness personally for gout, 3340. Would like to know when he was taking it in food, 3341.

Glacialine used in milk in Broadstairs, 3309.

Arcticanus used in milk in Broadstairs and the Isle of Thanet. Supplied from near Southampton, and pressed on dairymen, 3309. Basis unknown, 3310. Relation with intestinal mischief when used in milk thought of, 3334.

Formalin used because and since boracic acid has been detected in milk, 3311.

Benzoic acid used in France because and since salicylic has been detected, 3311.

Declaration of the presence of preservatives should be obligatory, 3312.

Injury held to have followed medicinal and surgical use of boracic acid, 3304.

**SANDES, CAPT. THOS. WM. (Digest of his evidence.)**

Started one of the first creameries in Ireland, in 1885, for butter-making, 77-78; saltless butter made with 1 lb. of preservative, and mild salted butter with, in addition, 3 lbs. of salt to every 112 lbs. of butter, 79; salt almost entirely replaced by preservative, English customers no longer taking heavily salted butter, 80; the latter contains 6 to 7 per cent. of salt, 84. Return to heavily salted butter impossible, 89.

Boracic acid used with the butter, alone or blended, 81-82; preservative never analysed, 83.

No complaints of use of preservative known; butter thus treated known to have kept a month, 87; it is necessary that it should keep a month, 107.

Preservatives have revolutionised the Irish butter trade, 88, but have not affected prices, 90-94; mixture with butter very intimate, 95-96; preservative very exactly weighed, 97, and the same proportion used all the year, 104; procured from Limerick firm of chemists, 98; only one kind used, 100-101; called boracic acid, 102; use advised by sale master as indispensable, 122; none used in milk prior to its reaching the creamery, 124; milk comes a distance of three miles at most, 125.

Saltless butter must needs be good to fetch its price; it fetches a better price than salt butter, 94, 105; very little made in winter, 105.

Mild-cured butter still marketable, 84; some people prefer a flavour of salt, 85-86.

Winter butter—stall-fed cows—not so good as grass butter, 105.

Experiment made with differently treated butter, resulted in favour of samples in which 1 per cent. of boracic acid used; those samples good at the end of nine months, 107-10; heavy salted sample was bad and uneatable, 109; butter need not for trade purposes be kept so long, 111-12.

Butter made expressly for English market, 113; weekly turn out, nearly a ton of butter; 1,000 cows supply the creamery, 123.

Danish methods of treating butter, under instructors, adopted, 115-16. Preservatives used in Denmark, otherwise the butter would not keep; their use winked at, 117-19; Danish instructors do not advocate boracic acid, but others do so, 120.

Hot weather sends butter bad in two days, 118: the butter would be rotten in a week, 120 no matter how prepared, 121.

**SCHIDROWITZ, DR. PHILIP. (Digest of his Evidence.)**

Doctor of Philosophy of Berne University, 7216, F.C.S., Analytical and Consulting Chemist, &c., 7217.

Beer, as preservative, subject of evidence before Beer Materials Committee of 1898, 7218-22 (App. No. 34).

Use of salicylic acid decreasing and of sulphites increasing, 7247-49.

Experiments made demonstrate preservatives to be unnecessary in refrigerated milk, 7223, 7230-31. Experiments described, 7224-29. Cooling of milk and storage at moderate temperature of vast importance in relation with keeping power of milk, 7233, and would obviate need for preservatives, 7234. Lactic acid bacteria less resistant to preservatives than other bacteria, 7245-46.

Cooling of milk should be enforced by Statute, 7235-37, under adequate inspection, 7238, 7242-44, though difficulty might arise as to enforcement, 7239-41. Initial cooling would allow of transit without material raising of temperature of milk, 7250; but refrigerator cars would be a great help, 7251. For cooling, 15° C. regarded as practically best, 7233, 7237, 7252-55. Maximum temperature of experimental milk in transit, uncooled, was 29.5° C., 7256-59; in milk cooled to 10.5° C., it was 11° C., 7260-61.

SHANAHAN, MR. HENRY. (Digest of his Evidence.)

Appears on behalf of the Cork Butter Exporters' Association, 341.

Butter could not be kept with one-half per cent. of preservatives, 343, as one-half per cent. of boracic acid itself is requisite, 344-45; necessitating three-quarters per cent. of preservative to be added, 376. Butter used to be passed through water, in which boracic acid had been dissolved in larger quantity, but the borax would not dissolve in the butter, 349, 351.

Boric glyceride, containing boracic acid and glycerine, an unworkable preservative, 347.

Boracic acid by itself used as a preservative, 348; but discontinued because found to be insoluble, 349; it was used in solution in hot water, which was allowed to cool, 350; as a preservative boracic acid has led to great improvement in butter manufacture, 385-86.

Preservatives generally insoluble and unworkable, 346-47; that now used in a dry form, 350; and added to butter before the salt after extraction of the butter-milk, 352-56; one-half per cent. of boracic acid added, 354-55; requiring three-quarters per cent. of the preservative, of unknown composition, 375-78. Preservatives prohibited in Denmark, but butter trade not thereby affected, 357-59; prohibition in Ireland would lower the value of butter all round, 361-62; and injuriously affect the farmers, 412. Preservatives are essential to the Irish trade, 363; and enable summer butter to be kept until needed, 390-94; price thereby regulated and market demands met, 395-97. Current prices largely determine the time butter is kept, 398; but prices do not affect the use of preservatives, 405-12. The effect of preservatives is to obviate a glut on the market, 413-14; they could not be dispensed with in perfected manufacture in Ireland, 441, because of poor keeping quality of butter, 442-49. Preservatives do not arrest putrefaction, 483-84; they are not added by suppliers of butter to the creameries, 486.

Factory butter processes described, 350; butter of different farms generally blended, 367, but only uniform qualities so mixed, 368. Factory and creamery system of manufacture a great improvement on old system in Ireland, 387-88. The factories in Ireland are on the Normandy system; the creameries in some of which Danes are working are on the Danish system, 488.

Butter-milk and water squeezed out of factory butter, 351; retention of butter-milk militates against keeping quality of butter, 387-88.

Danish butter naturally of better keeping quality than Irish, 364, because of cattle, their food, and land, 365-66; it deteriorates in price if kept over a week, 379-80; does not keep in a fresh state like Irish heavily-salted butter, 399-400; and has preference of sale in retail dealers' hands, 401-3; dairying carried on all the year round in Denmark, 415.

Irish butters of adjoining farms vary in keeping quality, 365-66. Manufacture improved by factory and creamery systems and the introduction of boracic acid, 387-89; preservative butter known in the trade to keep well, 398; when heavily salted the butter will keep better than Danish butter; the latter gets preference of sale by the retailer, 399-403. Practically no dairying in Ireland in winter, 416-19. Butter delivered to creamery or factory once or twice a week, 457-58, 485, and sent out as a finished product daily, 459; average maximum period of keeping it a fortnight, 460-64; sold thereafter as cold store butter, 465-68; some mild salted butter will keep three weeks without preservative, 469-72, 477-78, in cool weather; but not so all Irish butter, 473; some will not keep a week, 474-76. Period of lactation of cow not known to 3017.

affect keeping quality of the butter, 479-82. Manufacturers have nothing to learn from the Danes, 487. Refrigerated butter found to keep best if preservative had been added, 381-84.

Salt needs to be evenly distributed in butter, 387.

Soil an important factor in determining the keeping qualities of butter in Ireland; limestone yielding softer butter than brownstone, 420-34; even when butter is salted, 435; the soft butter might have a heated smell, 436-37.

Rancidity of butter caused by imperfection of manufacture, 438-40.

Colouring matters used to keep butter colour uniform, 369. Danish butter colouring used, 370, composition unknown, but quantity required is small, 371-72; obtained from Copenhagen, through a Dublin agent, 373-74.

Milk for butter-making pasteurised, before creaming, 449-54, to rid it from feeding taint, 455-56.

SINCLAIR, MR. S. GIBSON. (Digest of his Evidence.)

Represents the Liverpool Provision Trade Association, 934.

Borax packing can be done with thoroughly cured and very dry bacon so as to keep the meat considerably over a month, 935, 943; its prohibition would kill the Canadian meat trade. No Canadian meat comes salted, 936. Borax practically all washed off the meat over here, 945. No injury to health from eating boracised meat known. Has eaten a great deal without any ill effect, 947.

Curing "thoroughly" a matter of time of keeping meat in salt, 943-44.

Refrigeration of American meat unsatisfactory by reason of loss of flavour in thawing out, and tendency to go bad, 936-37.

SMITH, MR. THOMAS CARRINGTON. (Digest of his Evidence.)

Dairy Farmer, County Councillor, and represents the Central Chamber of Agriculture, 4407-9, 4523-25.

Preservatives in dairy produce opposed by the Central Chamber of Agriculture by formal resolution, 4410-11, 4487. Preservatives advertised at Islington Dairy Show, 4540-44. List of preservatives handed in, 4544-47. (App. No. 11). Preservatives held to be seldom used by farmers, but often by dealers, 4549.

Prohibition of preservatives and colouring matters in all dairy produce and margarine desired by Central and Associated Chamber of Agriculture, 4487. Motive mere guess work, 4554-57. Staffordshire Chamber of 200 members, mostly farmers, favour colouring of cheese, but would prohibit it in milk as fraudulent, 4488, 4490-91, as also in margarine, 4489, 4521-22, and the resolution to this effect emanates from men doing a very considerable milk trade, 4492-4503. Prohibition of preservatives might temporarily restrict the milk supply, 4549, and raise prices for a short time, 4549.

Milk trade would not be interfered with if preservatives were prohibited, 4413-14, or only temporarily, 4549. None used by witness in sending milk to London from Mid-Staffordshire, 4414-15. No complaint of milk lost save as to Sunday milk sometimes, 4416-18, 4515. All save Sunday milk in consignees' hands in twelve hours, 4419-24. During four winter months milk only sent out once a day, 4425-27. His milk goes to Birmingham now for reasons of price, 4550-52. Milk from Aylesbury Valley sent to London without preservative, 4428-30; but milk cooled, 4431. Also from Faringdon, Berkshire, in large amount, 4440-41, 4539, and from a point equidistant with Staffordshire, from 1,500 cows, 4443-46. Cooling and straining of milk render preservatives unnecessary, 4515, in any part of England, 4549.

Cooling of milk essential, 4431. Apparatus of cold water tubing used, 4432. Some farmers do not command the needed water supply, 4433, which is necessary to long distance milk transit, 4434. Cooling chambers should be used by the consignees, 4434-35. Railway vans should be such as to keep milk cool, down to 60° F., 4435-39. Cooling of milk, plus cleanliness, keeps milk sweet during transit, 4504. Witness sieves milk three or four times and is particular as to cleanliness of cattle and sheds, 4505, and these have their effect on keeping power of milk, but cooling the most im-

Précis.

**Précis.**

portant factor, 4506. No difficulty in the way of all milk being sieved, 4507-14, but difficult to get it done, 4516. All dairy farmers ought to have a good water supply, 4517-20. Dairies, &c., Order ought to be enforced, 4526-27, 4531. Drought at times a difficulty as to water-supply, 4528-30. Only cool water needed for refrigerating, 4531-34, even catch water suffices for witness, 4535-37, milk not coming in contact with it, 4538.

Keeping quality of milk affected by temperature, 4427, but greatly dependent on cooling, straining, and cleanliness, 4504-15.

Cream more likely to sour than milk, 4447, but point not personally vouched for, 4448-53.

Butter made, and no preservative used, 4454-55, 4473. Conditions of trade have changed, 4456.

Injury to health witness's reason for objecting to preservatives in milk, 4553. Butter not on the same footing, 4558-60. No case of injury known as regards preservative dairy produce, 4561-64.

Colouring matters in dairy produce opposed by the Central Chamber of Agriculture by formal resolution, 4410-11, 4487. None used in butter made by witness, 4454-55, 4473, but used in cheese, 4457, for purposes of price, 4458-60, and to supply local demand, 4461, annatto being in question, 4462. List of colourings handed in, 4463-66 (App. No. 11). Annatto in chief use, 4467-70, but other colourings advocated by leaflets, &c., 4469, 4471-72. Colouring used by 64 of 100 farmers, dealers, &c., replying to questions as to dairy products, 4474-76. Colouring of cheese quite a supply of demand, 4477-78, and a matter of locality, 4479-80. Colouring not needed for butter, 4481-82. Food and breed of cow affect colour of butter, 4482-86.

**SORENSEN, MR. CARL W. (Digest of his Evidence.)**

Consulting Expert to the Manchester Pure Milk Supply Co., 6992, and formerly Chief Dairy Expert to New Zealand Government, 6993. Was seven years in New Zealand, 6994.

Preservatives first used experimentally in a few tons of butter, 6995; commercially nothing was gained by using them, 6996, but one or two boxes were reported to be very fine, 6997-98. Use given up, as expensive, 6999, and London Agents quite satisfied, 7000. Opinion was divided in New Zealand a few years back as to preservatives, 7001. Of circularised factories, 60 per cent. deemed them to be unnecessary or useless, and only 20 per cent. were in favour of their moderate use, 7002. Some of latter, largest exporters in the colony, 7003, and advocated only  $\frac{1}{4}$  per cent., 7004;  $\frac{1}{2}$  to  $\frac{3}{4}$  at the very outside, 7005. At the time witness left the colony, two-thirds of butter reaching England was not preservative, 7006-7. Present condition of affairs not known, 7008, 7129, but reason to think increase of use since leaving, 7009. No doubt some pressure has been exerted, 7010-12.

Experiments made with preservatives, as chief dairy expert, 7013, showing slightly greater keeping power of chemically treated butter, 7014, the flavour being better preserved, 7015,  $\frac{1}{4}$  per cent. being the amount admixed, larger quantity flavouring the butter, 7016, giving it a saline taste, 7017. Experiments left witness unconvinced as to desirability of preservatives, 7018-21.

Prohibition of preservatives has been held to be likely to advance the price of milk, 7114. It need not do so, as evidenced by Copenhagen and Manchester, 7115.

Milk of Copenhagen Milk Supply Co. not preservative, 7022. No preservatives used in milk supplies of towns in Denmark. They are strictly prohibited by law, 7023. They may be used in small villages, 7024, where the law is not so strictly enforced, 7024-27. Dr. Stein known by witness years ago, 7028. He is official analyst to Danish Government, 7029, and his functions extend all over the kingdom, 7030-31. Quite possible to supply large towns with unpreservative milk, 7032, 7043. Manchester Pure Milk Supply Co. use no preservatives, 7033. They get milk from nine farms, 7048-49. Have existed for one year, 7050. Trade increasing, 7130-31. Customers of mixed, but chiefly of middle class, 7151-53. Sanitary conditions of lower classes in English towns perhaps not so favourable to keeping milk as in Copenhagen, 7154-56. Only one delivery of milk daily at Copenhagen, 7034, with advantages affecting con-

sumer, 7035. Cleanliness and prompt cooling of milk enable one delivery to suffice, 7036. Cooling is relatively expensive, requiring ice, 7037, a commodity more easily obtainable here than is imagined, 7038-40, though difficulty may occur in parts, 7136-38. Ice preserved by stacking, 7041-42. One delivery daily would compensate for cost of refrigeration, 7044, and cheapen milk, 7045, with tendency to concentration of vending, 7046, but not of dairying, 7047. Equality of milk standard would also result, 7051-52. One delivery daily suffices for Manchester; hence also probably would for London, 7053. It is now welcomed in Manchester, 7059. Ice is requisite, 7132, but not for delivery twice daily, 7133-35. Manchester supply from places comparatively near at hand, 7054-58. Milk sufficiently cooled will travel 200 miles equally as well as 50 miles, 7058. Contracts of Manchester Pure Milk Supply Co. very stringent with farmers, and milk-cans cleansed before return, 7060, and farm water supply looked to, 7061-63, and cooling of milk to 40° insisted on, 7064, as requisite to a daily delivery, 7139-40. Price none the less lower than average vendor, 7064, 7158-60, and foot-note. Three per cent. of fat stipulated for, and all milk tested; average 3.5, 7065-70. Has fallen to 2.7 on a single day in August, 7071. Calving is regulated on a fixed basis, 7072-75. Milk is received in sealed churns, 7076-79. Separated milk dealt in, 7080-81, demand being some 6 per cent. of whole milk demand, 7082. There is annatto in most milk, 7083. Evening and morning milk differ in quality, 7093-96, and evening milk may be diluted to quality of morning milk, 7097-98. Desirable to stop the fraud of selling separated milk as whole milk or admixed with whole milk, 7084-7113. Customers of Manchester Pure Milk Supply Co. dealt with directly, 7157.

Pasteurising of milk in Denmark and Copenhagen not universal, 7171-74. Manchester Co. opposed to the practice, 7175, 7183, as unnatural and injurious, 7176, on medical advice, 7177, as rendering milk indigestible, 7178. It caramelises the milk sugar and coagulates the albumen, 7179, and flavours the milk, 7180-82.

Cream needs no preservatives if traded by proper channels, 7116-17, daily, 7119-20. The grocery trade has made them requisite, 7118. None used in Copenhagen, 7120, with extremes of temperature, 7121-22, and cream travelling three to five hours, 7123-24. From 140 to 150 grains of boracic acid found per gallon of cream taken haphazard in Manchester, 7141-45.

Boracic acid in 1 per cent. solution tastes butter, 7125-28, 7146-50. Two per cent. would render butter useless for this reason, 7161-63.

Transit of butter in refrigerator cars in New Zealand, 7164, and of butter and milk, also in Denmark, 7165-68. None such in Manchester, 7169-70.

**STARLING, DR. E. H. (Digest of his Evidence.)**

F.R.C.P. and F.R.S., 6933, and represents the Royal College of Surgeons, 6934.

Preservatives heard of as being most in use are formalin, salicylic acid, boracic acid, and borax, 6935-37. Use of preservatives of interest to medical profession, especially as to salicylic acid, 6967, in cases of rheumatism, for example, when results might prove to be very serious, if the amount were taken also in food, 6968, 6970, salicylate of soda being in question, 6969.

Harmful effects of borax and boracic acid as medicines vouched for on much evidence, 6944. Infantile scurvy might be produced by borax, 6945. Sterilised milk not likely to produce scurvy—that is malnutrition, 6946. Infantile scurvy said to prevail most in higher classes, 6947-48, who use most sterilised milk, 6949, hence cause and effect presumed, 6950-52. No direct experiments made, 6953. Unlikely that borax taken continuously can be other than harmful, 6955. Harm to infants from boracised milk known of, 6956. Irritant properties of sodium sulphite comparable with boracic acid, 6979. Has never prescribed the sulphite, 6980.

Contra-indication of salicylic acid in cardiac weakness, 6971, 6971\*. Its indiscriminate use objected to, 6972. Boracic acid contra-indicated and dangerous in any lesion or disease of intestinal tract, 6973. Dangerous to feed a typhoid patient on milk containing 20 grains of boracic acid per pint,

6974, or a diphtheria patient; both would take much milk, 6975-76. In healthy cases no cumulative effects of boracic acid, 6977. Internal application of boracic acid not known, 6978.

Experiments made as to physiological action of formalin and digestive action of salicylic acid, 6938; with formalin in  $\frac{1}{1000}$ , 6960-62. Formalin takes away food character of proteids, 6939. In  $\frac{1}{1000}$  formalin stops the action of pancreatic juice, 6963; not tested as to  $\frac{1}{1000}$ , 6964. Salicylic acid is less harmful than formalin, but is apt to cause stoppage of gastric digestion in the stomach, 6941. It is a potent drug, and should not be used unknown in food stuffs, 6942. Experiments on dogs do not show much against boracic acid or borax as used in foods, 6944. Experiments of Drs. Rideal and Foulerton as to formalin not known, 6957-59. Objections to formalin based on experiments showing its effect upon proteid and digestive activity, 6965-66. Experiments with artificial gastric juice are reliable, but harder on the antiseptic than those on the living subject, 6988-91.

Prohibition of formalin as a preservative should be absolute, 6940. Would feel inclined to forbid use of salicylic acid also, 6943. Would object to use of boracic acid and borax, especially in milk, 6944. Would not tolerate them in milk, 6954.

Prohibition of antiseptics in food advocated, 6986. Continued use of a preservative might have a tendency to diminish vitality of the human body, 6987.

Copper sulphate in peas will probably enter into combination with proteid constituents. Action of copper is very largely on the intestines, 6981-82. Is opposed to small amounts of copper for colouring peas, 6983. Would be dangerous taken constantly in  $\frac{1}{2}$  grain to lb. of peas, 6984-85.

STEVENSON, DR. THOMAS. (Digest of his Evidence.)

M.D., F.R.C.P., Public Analyst, &c., &c., 4796.

Preservatives in food studied, 4797. Those most commonly used in milk are boracic acid and formalin, 4804. Former said to have caused nausea in five grain doses, 4821. To taste a food it must be in excessive amount, 4832.

Sterilising of milk held to tend to innutrition, 4804.

Milk to Guy's Hospital found once to contain boracic acid. Preservatives now prohibited in the milk, 4798. Milk needs no preservative if properly cooled, and due regard paid to cleanliness, 4801. Large vendors use precautions which render preservatives unnecessary, 4802. Preservatised milk should not be given to the sick, 4803, 4806, because of effect on digestibility by the use of boracic acid, and hardening effect of formalin, even in small quantities. Children should not use preservatised milk, 4804. Stale milk may be sold by reason of contained boracic acid to prejudice of purchaser, 4826-28.

Formaldehyde in milk altogether objected to, 4829. If allowed, quantity should be very minute, and difficulty arises as to determining small quantities, 4830-31.

Salicylic acid affects individuals injuriously, 4823. Objection to its indiscriminate use. Non-injury of many does not confirm non-injuriousness as seen by plumbo-solvent water poisoning, 4824-25.

Contra-indication of heavily boracised milk in typhoid fever, 4807, and acute nephritis, 4808-9. Injury to individuals may result from the indiscriminate use of boracic acid and salicylic acid, 4810.

Infants relatively more susceptible to boracic acid and formaldehyde than adults, 4848-50.

Experiments by Dr. Annett as to boracised kittens of value, and should be carried on upon a larger scale, 4805. Committee should undertake experiments as to effect of preservatives on animals, 4811, young animals, 4812-13, as monkeys, 4814-15, but objection obtains to the latter on account of mortality among them, 4816-19. Home Office licence necessary, 4820. Such experiments would be valuable; controversies need settlement, 4846, and nothing better than animal experiments can be suggested, 4847. But the Committee should undertake such experimental work, 4854, on animals, young and mature, 4855-56.

Prohibition of preservatives advocated, though a little boracic acid in butter might be allowed, but not in multiple articles of diet, 4832-33. No one should

have more than 15 grains of boracic acid per diem under any circumstances, 4834-36.

Prohibition of preservatives in Guy's Hospital milk, 4798-99, as unnecessary and inadvisable, 4800.

Court of Reference as to preservatives and colouring matters would be valuable, 4851-53.

Colouring matters of late have undergone change for the better, especially in sweetmeats, no noxious dyes being now found, 4837, nor for 20 years past, 4838-39. Regulation a question of expediency. Colourings vary constantly, 4842. They should be scheduled, after experiments, 4843, which are essential, 4844-45.

Copper in peas used in diminished quantity, 4840. It should be prohibited, 4841.

STILL, DR. GEO. FREDERIC. (Digest of his Evidence.)

(Represents Great Ormond Street Hospital.)

Borax and boracic acid studied as regards children, 6784-86. In cases of  $2\frac{1}{2}$  grains of each to a pint of milk looseness of bowels has resulted. In another case distinct benefit accrued. Has given  $2\frac{1}{2}$  grains of each three times a day for epilepsy to older children, with good effect, when added with bromide, but looseness of bowels has in cases resulted, and in one instance the boracic acid had to be stopped, 6787-88.

Salicylic acid is commonly used, 6808.

Indiscriminate use of drugs as preservatives might be of serious moment for medical profession, 6806. 6810, especially as to salicylic acid 6808-9; but borax and boracic acid rarely used, and formalin never used internally, 6807. Physicians should know accurately the amount of drugs taken in food, 6810.

Harmful results may accrue from formalin as a preservative, but no considerable harm probably, 6816. It would interfere with digestion if long continued. Would be chary of letting children have anything containing it, 6817.

Milk should contain no preservatives if it can be guaranteed against going bad in consumer's hands without them. Some delivered to Great Ormond Street Hospital goes bad in summer by the time it reaches the children, 6789, 6813. Milk well cared for in the hospital, but two epidemics of diarrhoea definitely traced to bad milk there in summer, 6790. Desirable that hospital milk should be examined for preservatives, 6811. It could be done by arrangement outside, 6812. No preservative found in milk specimens examined from Great Ormond Street Hospital, 6814.

Sterilisation or pasteurisation and even boiling of milk held to be harmful to children, 6791, 6799, especially the former, 6800. Infantile scurvy or mal-nutrition follows prolonged heating of milk to a high temperature, 6792-93. Reason not known, fact remains, 6794, and is well recognised, 6795. The scurvy can be produced by almost any patent food, 6796. The disease increasing, 6797, and is due to such milk and foods, 6798. Freezing of milk might have like effect, 6801, moderate cooling would not, 6802.

Cream not much used in children's hospitals, 6803. Used chiefly for marasmus, 6804. Same objections apply as to preservatives as in the case of milk, 6805.

Butter going to Great Ormond Street Hospital has been found to contain 17.4 to 47.6 grains of borax per lb., and has been given to children, no ill results noted, 6814. Very little taken, and that only by a few, 6815.

Experiments *in vitro* not deemed important, 6818-20.

SYMONS, MR. HENRY. (Digest of his Evidence.)

Partner in firm of Messrs. John Symons and Co., Cider Merchants, 7262-63.

Preservatives in cider used by best makers in small quantity, 7264-65. Salicylic acid, saccharin, sulphite of lime, or soda used, 7266, the saccharin being soluble, 7267, a product of coal tar, 7268-69, identical with "Tigress Brand" of saccharin, 7270-72. Preservatives good in small quantity to arrest viscous fermentation, 7273-77. Has used preservatives hitherto under certain conditions, 7278-80. They should not be prohibited but limited, 7281, as to quantity, 7282-84. Salicylic acid not always used and only a small quantity at any time. A standard should be fixed, 7285; not more than  $\frac{1}{2}$  to 1 oz. of

Précis.

Précis.

salicylic acid per 116 gallons, 7286-87, and  $\frac{1}{2}$  to  $\frac{1}{4}$  oz. of saccharin, 7288. Beer showing incipient taint would be beyond the aid of saccharin, 7289, as also would cider. Preservatives should be used from one to three months before public get the cider. Salicylic acid held in Court to do more good than harm as used in cider, 7290. Only best makers should be allowed to use it, 7291-92. Too much preservative might be harmful, 7305. From 1 to 2 oz. of soda would be used per pipe, 7306. About  $\frac{1}{2}$  more used in America, 7307-9, and in Germany saccharin and salicylic acid used largely, 7310, about one-third more than above suggested standards, 7311. Has never used as much as Germans or Americans, 7312. A witness holding that preservatives are not needed in cider not one having a great experience, 7293. Pure cultures can be obtained for beer manufacture, 7294-99. Has isolated pure yeast from apple pulp, 7300, and has identified the organisms concerned in cider manufacture, 7301. There are many kinds of germs, yielding differing results. A constant germ might obviate need for preservatives in cider, 7302-4. Cleanliness no substitute for preservatives, 7313. Difficult to exclude such bacilli in cider making as to obviate use of preservatives, with a weak percentage of spirit, 7314-17. Sick cider would not be salicylised, 7318, but with indications of going wrong the acid would be added as a preservative, 7319-23. Such indications are exceptional, 7326. Pasteurising does not work well, 7324. It causes insipidity. It is practised in France and Germany, 7325. Too late to pasteurise cider quite ready for consumption. Preservatives in cider not universally advocated, but honest traders should be permitted to use a small quantity in case of necessity, 7327, 7335. Cider industry very ancient, 7328, but progressive, 7329-30. Perfection of keeping cider probably attained, 7331, and knowledge has followed experience, 7332, by the aid of bacteriology, 7333, 7335. Difficult to say if manufacture of cider has improved, 7334.

TRENGROUSE, MR. HENRY. (Digest of his Evidence.)

Appears on behalf of the London Chamber of Commerce, 612. His firm represents the packing house of Armour and Company, of Chicago, 611, 615. Mild-cured provisions preferred now, 614, and produced in America, 616. Hard salted bacon and hams and no other from America years ago, 615. Salt conceals defects in produce, 656-57. Salted meats not now saleable, 665. Bacon and hams come from America dusted with powdered borax, 618, which is washed off, 619. Boracic acid chief preservative used, 617-18. Is intimately mixed with butter, 625, 628; probably mixed also with French butter, 627. Factories advised to use one half per cent., 646; but two per cent. said to have been found in some Australian butters, 647-48. No stipulation made as to percentage to be used; traders at mercy of shippers and manufacturers, 649. None added by witness's firm, 651. It does not conceal defects of butter, 655. Would impart flavour only when largely employed, 658. It may be added both at creamery and factory, 659, 662. Use needs systematising and standardising, 660, 702. Second dosage obviated where butter is made at the creamery, 664. Highest percentage known in butter is three, 678. Is superior to salt as a preservative. No ill effects heard of from its use, 702. Prohibition of boracic acid would result in a return to salted butter, 703. Butter brought largely from Australasia, 620, in cold chambers, 623, unsalted but with boracic acid in it, 621-22, and will keep out of cold chamber for two or three weeks, but without boracic acid would deteriorate very rapidly, 624. This butter improving and coming into favour at lower prices than Danish, 650. Moist butters of delicate texture call for preservative, 652; Australasian butter does so, 653, 673. It passes from creamery to factory, 662. All stock more than a week old is cold stored, 665. The butter ought to be made to keep a month out of cold store, 666-73. It is on shipboard five to six weeks, 677. Plenty quite as good as Danish, 689. Its introduction has brought down Danish prices, 702. Danish butter believed not to contain any preservative

but 1 per cent. or more of salt, 630, 654; difficult in keeping it, 631, 654; but it is very solid and free from moisture, 635, 674-75, and thus keeps longer than Brittany butter, 694-96. Forms bulk of English trade, 679-81, 683-85, 693; short voyage obviates need for preservatives, 682; none save salt is used, 686-87. The Danes get on without, 688. The butter commands a high price relatively 697; is chiefly used by the middle class, 698.

Normandy butter needs rapid consumption, 632, also Brittany butter, 633, which soon goes off unless preservative be used, 634. More moisture in these butters than in Danish butter. Brittany butter creamy, demanding day by day consumption, 635-36. It is factory made, 637. Normandy and Brittany butters most in demand in London, 692. Brittany butter commands the highest price, 698.

Irish butter could be introduced for immediate consumption without preservatives, 690-91.

Moisture of butter determines its price, 699, and keeping qualities, 700-1.

Colouring matter, annatto, used for butter at most factories, 638-39, and largely for cheeses, 643-45.

Tinned meats slightly salted, 642.

TUBE-THOMAS, MR. JOHN. (Digest of his Evidence.)

County Medical Officer of Health for Wiltshire, &c., 4923-25, 4947, 5046-48.

Diarrhoea in children found to get worse when treated with 1 to 5 grains of boracic acid in their food, 4926, in Newport (Mon.), 4927, an industrial town; the milk ordinarily taken by the children containing from 40 to 120 and more grains of boracic acid per gallon, 4928, as ascertained by analysis and by the word of the milk vendors, 4929, who added the acid under a fancy name, 4930. Many children in question, 5001, at all seasons, 5050, for twelve months, 5051, in one locality, 5002; no multiple attacks in houses, 5003. Milk drinkers alone attacked, 5004, 5008, and all milk from one source, 5005, 5007, which hit all children alike, 5006. Other similar experiences had, 5052-54. Diarrhoea rate among children thought of as influenced by preservatives, 5009-10. The disease induced in phthisical persons on boracised milk diet, 5024-25. Doubtless the experience recorded above regarded as exceptional because of want of knowledge on part of medical profession, 5055-56. Boracic acid, salicylic acid, formic aldehyde prescribed by witness for diarrhoea and indigestion, 5056, but not since above experience, 5058, as no control can be had over the doses taken, 5059-61. Dose of boracic acid reduced 50 per cent. in new edition of Pharmacopoeia, 5062.

Milk of high-class dairymen not so much boracised as of "over-day" milk vendor, who may doctor milk already treated, 4932. Boron compounds also used in private houses, 4933. Milk needs no preservative, 4934, even in the case of a large town, 4935, cleanliness being an absolute necessity, 4936-37, 5039-40, and preservatives putting a premium thereon, 4938, 5027-32. Milk is recklessly boracised, 4942-43, and trade by its use improperly carried on, 4944-46, and gross neglect of ordinary precautions and sanitation found where preservatives used, 4948. Milk should be consumed within forty-eight hours of being drawn, 4949. In midland and southern counties some 85 per cent. of milk consumed by children and invalids, 5021-23. Bacteria should be kept from milk rather than inhibited when there, 5026. Milk should be strained, cooled, and sterilised, 5039-40. Milk properly treated will keep forty-eight hours under all circumstances, 5041-44.

Pasteurisation used by some Wiltshire and other dairies, 4980, 4983-84, 4986. Trade springing up, 4982. Milk is bottled, 4985, at same price at Leicester, 4987. Exact temperature not known, 4988.

Transit of milk by rail may need improvement, 4970. At present harm may accrue, 4971-73. Matter easy of rectification, 5045.

Butter not in same case as milk, qua use of preservatives, 4950-51. A difficulty arises in supplying large towns with fresh butter, 4952, at certain seasons, 4953, but Danish butter largely imported, 4954-55, without difficulty. Australian butters are preservative, 4956. Many home creameries use preservatives, 4957. None known which do not, 4958. Witness would modify his view if he knew that large creameries did not use them, 4959-60.

Boracic acid used for dusting poultry, 4938, and recklessly used in milk, 4942-43. Also used for sausages, up to 80 grains per lb. in November, 4973, such quantity being recommended in the pork trade, 4974. Boric Syndicate pamphlet issued with one object in view, 4989, and is a collection of data, 4990, leaning one way, 4991, towards favouring boric compounds, 4992.

Formalin getting more used by dairy people, 4975-76.

Idiosyncrasy of witness to boracised milk and food, and to boracic acid as a drug, 4930, 5014-15. Most children and invalids idiosyncratic to preservatives, 5016.

Physiological action of boracic acid is to cause a certain amount of skin eruption, 4931. Medical profession generally ignorant of the injurious effects of boracic acid. Evidence in the pamphlet of the Boric Syndicate not altogether satisfactory, 4938-39. Harm held to result from administration as a drug too soon after food, 4939-40, and indiscriminate use objected to, 4941, as well as use unknown to the consumer, 4942. Formalin injurious if taken continuously, 4978. If medical men were aware of the substances used as preservatives and the extent to which used, mischief thereby would be looked for, 5011. Parallelism of lead poisoning and ergotism, 5012-13.

Sanitary improvement in rural districts put back by use of preservatives, 4946, 5027. Some farms in such a state as to render milk impossible of delivery without preservatives, 5027-32. Dairies, &c., Order not generally enforced, 5033-36. Proper water supply would result from enforcement, 5037-38.

Experiments on dogs of little value as compared with the human economy, 4993-96, so with cats, and in the laboratory, 5067-69. Kittens more nearly approximate to the human, 4996-99. Experimental evidence thus far not decisive, 5000, 5063, or satisfactory, 5063-66.

Declaration of preservatives not desirable, rather to be avoided, 4949, and not sufficient *quâ* children and invalids, 5017-20.

Prohibition of boracic acid in milk necessary; milk most largely used by children and invalids, 4932, 4934. All preservatives unnecessary, 4977.

Colouring of milk should not be allowed, 4961, 4968, because fraudulent, 4962. Not believed in or butter, 4963, nor for cheese, 4964-67. Should not be allowed in cream, 4969, or butter, or marg rine unless it be very distinctly tinted, 4969, to prevent fraud, 4970. Colouring used for sausages, including rose pink, 4973.

VASEY, MR. SAMUEL ARCHIBALD. (Digest of his evidence.)

A Fellow of the Chemical Society, &c.; represents the "Lancet," 1975-77.

Examinations made of food and beverages over a series of years, and several preservatives found, and in some instances as a result of comment afterwards discarded by vendors, 1978-85. Exclusion of salicylic acid from beverages was made on account of hurt to trade by its known inclusion, 1986. Vendors of preservatised articles nearly always communicate with "Lancet," 1991.

Preservatives increasingly used, 1995, and at certain seasons cannot be dispensed with, 2003. Limit to their preserving power, 2004, and this fact important, 2056-57. Borax or boracic acid most frequently used, 2037, then salicylic acid, 2038, then formaldehyde, 2040, then benzoic acid, 2039, but only a few instances found of latter, 2043. Use of formaldehyde increasing, 2041; not so salicylic acid, 2042. Fluorides not found, 2044, though heard of in food, 2045. Use of benzoic acid and formaldehyde should be prohibited, 2046. Preservatives should be allowed in summer, 2047-48, in milk products, 2049. Public not self-protected against the addition of preservatives, 2065-66. Dates of use of preservatives becoming known, 2079-85. (App. No. 10.) Preservatives in food held to be injurious to health by medical men and physiologists reporting to the "Lancet," 2101-6.

Boracic acid and borax both found in food samples, 1987-88. Analysis made not quantitative, 1988-90, such analysis difficult, though accurate, 2036.

Copper in peas, 6 grains per lb. found, 2005, 2007, 2097, effect on consumers not known, 2008. Small portions of peas not sufficient for examination,

whole lb. desirable, 2006. Copper not present as copper sulphate, 2009, but as a proteid compound, 2010, not soluble, 2011, though possibly soluble at times, 2012-13, as in the human economy, 2086-87. Distribution of the copper unknown, 2014, likely to be mostly on outside of peas, 2015, absolute uniformity of distribution not expected, 2019, though borne out by careful analyses, 2024-25, 2028-29. Put in to preserve colour, 2016. Some tinned peas contained no copper, 2017, 2030, but they were off colour, 2031-35. The physiological action of the copper must determine the question of its use or disuse, 2018. Difficulty in defining limit of quantity to be used, 2019-20, and of conviction on basis of quantity present, 2021. Limit should be determined, 2022-23. Declaration of presence sufficient if addition decided to be objectionable, 2026-27. Use prohibited in France, 2088, and prohibition recently withdrawn, 2089. Dangerous to add  $7\frac{1}{2}$  grains of metallic copper per lb. of peas, 2093. Declaration of amount of copper unobjectionable, 2094-96. Largest amount found not known, 2097-98.

Milk for infants and invalids should contain no preservative. London general hospital milk samples were found to contain boracic acid, 1992, 2099, 2100. Milk products should be guardedly preservatised in summer, 2047-51.

Invalid foods should not be chemically preservatised, 1992. Practically all the examined samples some years ago were so preservatised, 1993, but later samples were free from preservatives, 1994.

Declaration of preservatives should be made, 1996, 2003, 2052-56, and would suffice, 2067-69, though not in cases where boracic acid is contra-indicated, 2070-74.

Standards limiting use of preservatives desirable, 1997-98, 2050-51. Unequal distribution in food no barrier, 1999-2001, 2003; maximum limits should be insisted on, 2058, 2076.

Classification of foods *quâ* use of preservatives desirable, 2002, 2050, 2059, and feasible, 2003, 2060-64. Purchaser should be able to procure an article free from preservatives, 2003, 2052, 2078.

VOELCKER, DR. J. A. (Digest of his Evidence.)

Appears on behalf of the Royal Agricultural Society, 1635.

Preservatives examined, 1636, 1639, mostly those used for milk or cream, 1637, 1639, 1652. Could draw no clear distinction between those used for milk and cream, 1638. Not found in milk samples sent by farmers themselves, but only in those under the Food and Drugs Act, 1644. Not personally responsible for analyses referred to in evidence as made under the Act, 1670. No check on amounts used; this a great danger, 1676. Clear distinction between their use in milk and in cream and butter, 1692, 1748. Preservatives permit of goods being sold which should not be allowed, 1714, and which would decompose but for the contained preservative, 1715. Preservatives in milk should be prohibited, 1716. No wide experience of preservatised foods, 1757.

Declaration of use of preservatives should be obligatory in milk and cream, 1716, 1749.

Quantity of preservative in milk and cream should be limited and standardised, 1749-50.

Boracic acid preservatives commonest in milk, 1639, 1643.

Salicylic acid used in milk formerly, not recently found, 1643.

Formalin never yet found in milk, 1643. It renders food indigestible, 1817.

Butter samples frequently boracised, 1652, some home and some Colonial, 1653. Only boracic acid preservatives plus salt found, 1654. Australasian butter with and without preservative kept equally well for six weeks, 1682, 1723-29. Quite possible to send the butter without preservative, 1683, 1720-22, 1730-32. Proportion so sent not known, 1684-85. Australian butter samples were examined about June last, 1702-3, six in number, 1717-19. Rancidity could hardly be masked by preservatives, 1714. Different pastures said to produce butters of different keeping qualities, 1733. Is sceptical on the point. Butter properly made under proper conditions requires no preservative, 1734. Sterilisation not a necessity, 1743-47. Not aware that Danish instructors have failed in Ireland to produce butter of Danish keeping quality, 1735-36, 1739.

## Précis.

Milk preserved may furnish differing quantities of the admixture in different samples, 1640-41, 1671. Those containing preservatives mostly adulterated or mixtures, 1652. Preservatives may be repeatedly added to milk, 1672, haphazard, 1673-75. Samples examined not decomposed, 1698-1700. Decomposition does happen, 1701. If started it could hardly be veiled by preservatives, 1712-13, but the preservatives enable milk of bad keeping quality to be sold as good milk, 1715. Keeping quality affected by insanitary surroundings, 1739, and by health of cow, 1740-42. Milk is rendered indigestible by formalin, 1817.

Cream in jars often has all the preservatives at the top, 1642. Should contain no preservative without declaration, 1749.

Condensed milk sample (Australian) found to contain  $\frac{1}{2}$  per cent. of boracic acid 1645, 1648-49, in 1898, 1649\*, a high percentage, 1646, and not a safe one, 1647, and reckless, 1650. An exceptional case, 1677, and sent privately, 1678; reason not remembered. 1679-81. No need for a preservative in such milk, 1651.

Ciders, American, of low alcoholic strength and bad keeping quality, contain salicylic acid, some also glycerine, 1655-56. Quantity not determined, 1656. In 1895-96, 1657, samples brought by complaining English manufacturers, 1655, 1658. Ground for prosecution, quantity large, 1659.

Temperance drinks not examined, 1660.

Jams and preserves examined, 1660. One sample of strawberry jam had  $3\frac{1}{2}$  grains of salicylic acid per lb., 1661. Its presence objectionable, 1662-63, 1708, and used to cover imperfections, 1664, 1706. Not necessary in well made jams, 1664, 1704, or fruit pulp, 1706. Imported pulp cheapens the jam, 1707, and it is practically impossible to import pulp without preservative, 1708.

Rennet found to contain boracic acid preservative, 1685, the only sample examined, 1686.

Cattle food cakes, test samples contained borax purposely added, 1687, in cotton cake 1 lb. to a ton, to preserve colour, 1688, 1690, and may cover inferior make, and excess of moisture, which moisture may lead to fermentative changes, 1689-90. Such preserved cake has not been adopted, 1709-10. Borax not used in the trade, 1710, nor formalin, 1711.

Colouring matters found in jam, aniline dyes in sweets and pop-corn, 1666-67; no analyses made personally, 1668-69. No excuse for use of colouring in milk, it is usually fraudulent, and should be prohibited, 1691, 1748. Not so in butter, 1691. Butter alters its colour naturally. Usually fraudulent in margarine, 1692. Characters of colourings not much known, 1694-95. Colouring of peas not gone into much, 1696-97.

## WALFORD, DR. EDWARD. (Digest of his evidence.)

Medical Officer of Health for Cardiff, 1820.

Analysis of food and drugs to the number of 600 samples made in Cardiff annually, 1821-24. Population, 186,000 persons, 1909.

Preservatives reported on for Cardiff Town Council, 1825. Antiseptics, such as boracic acid and formalin, should not be added to food, 1826, butter and milk being the chief foods personally in question, 1827. Use of antiseptics general and increasing, 1828, 1853, 1921; boracic acid especially in question, 1854-55. Use unnecessary, 1837, 1886-88, though a trade convenience, 1838. Use may lead to lack of cleanliness, 1839. May conceal incipient decomposition, 1846. Proof of harm from preservatives would render them physiologically indefensible, 1872. Quantity used an important factor, 1873. Useful quantity very questionably harmless, 1874. Cooking would alter formalin present in food, 1918.

Prohibition of use of preservatives would not seriously affect urban milk supplies, 1909-10, 1928. Populous places better supplied with milk now than formerly 1911. Prohibition in Austria, France, and Germany, 1929. No reason why England should not follow suit, 1930-31.

Declaration should be made of the admixture of chemicals in food, 1836, but would not suffice, 1837, 1871. Public should be protected against chemicals in food, 1870.

Boracic acid is a drug, used medicinally, 1835. Some persons may be very susceptible to it, 1847, and

might take large amounts in food, 1848-49. It interferes with digestion, 1856, 1859-60, even in small quantities, 1857; this known from reading, 1858, of experiments made in laboratory, 1863-64. Experiments not regarded as typifying human conditions, 1865, 1898, and very trivial in their differences, 1866. Systematic feeding experiments would be important, 1899-1900. Poisoning cases not known, 1867, or heard of, 1868-69. Dose for a child some 3 grains, 1875. This should certainly not be exceeded in boracised milk, 1876. Sixty grains in foods in addition to the same as a prescribed medicinal dosage daily for an adult objectionable, 1877, and a danger, 1878. Many conditions under which medicinal use of boracic acid would be hesitated about, 1879-81, *e.g.*, pregnancy, 1892, 1884-85, and objection obtains as to its indiscriminate use in food, 1883. Cooking would not alter it, 1907-8.

Milk entering Cardiff boracised to some 8 to 13 per cent. of total samples examined, 1829-30. Quantitative analyses made, 1831. Lowest quantity of boracic acid found, 0.004 per cent., highest, 0.105 per cent., 1832; 0.05 per cent. would give 7 grains per quart; 0.1 would give 14 grains per quart, 1833. Such proportion might be harmful, especially to an infant, 1834. Use of preservatives in milk a serious question, 1927. Minute traces of formalin have been found in milk, 1840. Seasonal influence upon the presence of boracic acid not known, 1851-52. Powdered borax applied to milk and cream, 1901, and not always intimately mixed, 1902, thus tending to vitiate analyses, 1903. Sometimes sprinkled on top of cream, 1904, and hence located there, 1905-6. Strictly pure milk more important than unstinted supply, 1912-13. No preservative milk found decomposed, 1914. Cardiff milk supplied from its home counties, 1919, some eight hours old when handed to consumer, 1920.

Butter in 1898 found to contain boracic acid in 44.5 per cent. of samples examined, 1841. Proceedings taken in one case, 71.4 grains per lb., 1842. Warrant issued to dismissal of case, 1843-45. Percentage of 0.25 of boracic acid said to be needed to preserve butter, 1861, how long not known, 1862.

Bacon and ham not examined for preservatives, 1850.

Diarrhoea studied, 1889. Most prevalent during hot months, 1890-91, when most preservatives presumably used, 1892, and probably kept up by use of boracised milk, 1893. Mortality varies with summer heat, 1894. Sanitation ought to have reduced mortality beyond its present rate, 1895-96. Diarrhoea and milk diet closely related, 1897.

Ptomaine poisoning not a subject of study, 1915-16.

Colouring matters used a little, 1922, in milk and butter, 1923, in preserves, 1924, and preserved fruit and vegetables, 1925. No personal knowledge of use, 1926.

## WILD, DR. ROBERT BRIGGS. (Digest of his evidence.)

Assistant Lecturer on Materia Medica and Therapeutics at Owen's College, Victoria University, &c., 1413.

Boracic acid—doses personally taken of 10 grains at a time have not had any effect, 1416, no matter how or when taken. Acid tasteless; 15 to 20 grains not injurious in single doses, 1417, but continued daily doses of that amount for a week create slight disturbances, which soon cease on omission of the acid. Quantities up to 120 grains taken on occasion in some four hours, nausea and diarrhoea resulting, 1418. Has dosed patients with from 10 to 80 grains a day, 1420, in health and sickness, with benefit, 1421. Traces found in milk, 1442, of 1 in 1,000, 1443.

Excreted by the kidneys as an alkaline salt, and free boracic acid, according to dosages, 1419.

May safely be added in small amount in milk in health, 1429, 1444, 1 in 1,000, a quantity sufficing to keep milk for 24 or 48 hours, save in extreme heat. Not so with infants or in kidney troubles, 1429. An infant of three months would consume one or two pints daily, 1430, 1432, an adult on milk diet some two quarts, 1431, and 1 in 1,000 would give 9 grains per pint, 1433, a large dose for a baby, 1434, with resulting loss of appetite and nutrition if continued, 1435. Milk with a little preservative better than no milk, 1440, or sour milk, 1441.

Injurious effects, eruption, loss of hair, when 30 grains per diem taken, 1422, 1424-25, 1427, ceasing

on cessation of dosage, 1423, 1427. Patient an adult, 1424. Effect of doses cumulative, 1427. Temporary albuminuria caused, 1447. Possible ill-effects outweighed by benefits to infants of boracised milk, 1458. No ill-effects seen from five grain doses in any case, 1459-60. Ten grain doses have produced some seven cases of known injury, 1461, out of 40 treated cases; only three cases of albuminuria known, and in one, 20 grain doses used, 1462. Toxic symptoms may arise from idiosyncrasy or kidney disease, 1463-66.

Contra-indication to its use is kidney disease with albuminuria, 1447-50, and large numbers of persons thus affected, 1450-52, even before medical advice sought, 1456, and absence of boracic acid from their milk diet important, 1455, but often not effected, 1457. Other contra-indications are certain conditions of the stomach, especially of digestive organs in children, 1467-68, 1470-71, the latter a prevalent class in Manchester, 1469. No other conditions of contra-indication known, 1472. No personal experience of use, in pregnancy, 1473-78. Danger of giving boracised milk when kidney lesions in scarlet-fever present, 1497-98. Interest in the acid purely professional, 1487.

Declaration of its presence in milk important, 1436, 1444-46, 1453-55, and sufficient, 1488-92; but specific label desirable if possible, 1493-95.

Diarrhoea said to be less prevalent in certain children since boracised milk used,  $7\frac{1}{2}$  grains to the pint, 1480.

Milk partially decomposed may possibly be rendered saleable by boracic acid, 1481, and so may be conveying ptomaines to children, 1482, but matter not within the knowledge of witness, 1483. Milk sometimes containing no boracic acid in winter may do so in summer, 1484. Ideal milk would be without any preservative, 1493. Milk not injurious in enteric fever if only slightly boracised, 1496, but would not be given in scarlet fever, if other obtainable, 1497, and should be prohibited if intended for all cases of acute scarlet fever patients, 1498. Pasteurising practicable in Manchester, 1437-39.

Salicylic acid and formalin and copper in peas not within the knowledge of witness, 1485-86.

Colouring matters not specially worked at, 1487.

WILLIAMS, MR. WALTER COLLINGWOOD. (Digest of his evidence.)

Fellow of the Institute of Chemistry, Public Analyst, B.Sc., &c., 5145-46.

Preservatives in food studied, 5147. Boric compounds, formalin, and salicylic acid most commonly used, 5148. Borate found in sausages, pork pies, 5180. Boracic preservatives all mixtures, 5246-47.

Milk new and unadulterated seldom preservative, 5149, in Liverpool, 5155; in skim milk and separated milk borates more common, 5149, 5300, in Lancashire, 5150, and in towns with large proportion of poor people, 5392, outside county boroughs, 5151-54. Borates found most in winter, 5156, when milk is most valuable, 5157; but data are few, and the basis of statement not of much importance, 5197-5215. Milk should not be preservative, 5220. Supply of Liverpool can be carried on without preservatives, 5289-99. All milk samples examined for borates and formalin, 5300-4. Samples outside Liverpool hardly representative of Lancashire, 5305. Preservatives put a premium on cleanliness, 5306-7. Data as to milk sampling *quid* preservatives promised, 5391.

Butter found to contain boracic acid and borates only, outside salt, up to 62 grains per lb., 5169-70, especially in summer, 5171. Boraxed butter used for cooking (say) fish, would tend to saponify the fat, 5232-42. That preservative butter cannot be used for butter-scotch not known, 5243-45, 5248-50. Utility and necessity of boracic acid doubted, 5255, 5261.

Margarine samples nearly all contained borax or boracic acid, 5172, 5251-54. Mostly sold as butter, 5173-74, and much used in cooking; usually some 20 grains per lb., 5175. Utility of boracic acid or its necessity doubted, 5255-61, 5263, but trade seems to regard it as necessary, 5262.

Hams found to be cured with borax, with from 4 to 24 grains per lb. in the meat, 5176-77, the meat having been penetrated, 5178, some of the meat being foreign, 5179.

Bacon found to be penetrated by borates, 5180.

Cream samples found to contain boracic acid as a borate, 17 to 38 grains per pint, 5164-65, both potted and bottled, 5166. One sample unfit for use, 5167-68, and deemed to be injurious to health, 5325. Potted samples from grocers, 5221, who require the preservative to keep the cream, 5122-26, more than the dairyman, 5127-31.

Jam found to contain salicylic acid from  $\frac{1}{4}$  to  $\frac{1}{2}$  grains per lb., 5180. Bottled fruits and some jams found free from preservatives, which seem not to be needed in large, clean fruits, 5181, as opposed to small and easily damaged fruit, 5182. No proceedings taken, 5183, and difficulty apart from preservatives thought of as regards small fruit jams, 5184, but not upheld if makers do really get on without them;  $\frac{1}{2}$  grains per lb. in any case too much, 5185. Use not decreasing, 5264-67. Quality of fruit a prime factor, *quid* preservatives, 5268-71. With proper care all round, salicylic acid not requisite, 5272, and used, where used, often without thought, 5273, and its prohibition would not injure legitimate trade, 5274. One unpreservatised sample of jam contained mould spores, 5326-30. Imported pulps seldom preservative; preservatives unnecessary, 5331-35.

Temperance drinks found to contain much salicylic acid, 5186. Lime juice cordial found to contain from 20 to 108 grains per gallon; none is needed, 5187. The acid stops fermentation, 5188. Salicylic acid and formalin, and salicylic acid and boracic acid found in samples, 5189. Unsweetened lime juice, but no sweetened lime juice cordial, found unpreservatised. In lemon squash, 50, in ginger wine 118, in raspberry wine, 133, in orange wine, 106, and in black-currant wine, 140 grains of salicylic acid per gallon, 5190-92; and the acid found in herbal ale, 5277, all really non-alcoholic wines, 5193, 5285-88. Proceedings failed in cases where taken in Liverpool, 5193, because of medical evidence in favour of use of the preservative, 5194-95, and of evidence of manufacturers as to fruit used; but amounts recorded are above all requirements, 5195. Children principal consumers of above beverages, 5278-80, who might thus get large quantities of salicylic acid, 5281-84, 5308-11.

Formalin less frequent than boracic acid in milk, 5160. Amount in milk cannot be told with precision, 5162, but detectable in milk, 5163. Objected to, 5216, as affecting digestion, 5217, and as enabling stale milk to be sold as fresh, and as putting a premium on cleanliness, 5218.

Boracic acid objected to as a preservative in milk, 5218-20. Borax in butter used for cooking fish would tend to saponify the fat, 5232-42. No difficulty in determining quantity of the acid in food, 5313-15.

Experiments made with salicylic acid showed retarding effect on digestion of boiled white of egg, but not on pancreatic digestion, 5196.

Proceedings successfully taken in Liverpool for formalised milk, 5158, 5161; and unsuccessfully for salicylised temperance wine, 5158. Use of formalin was increasing, and was checked by the conviction obtained, 5159. Conviction secured because formalin an adulterant and deemed to be injurious to health, 5316-21. Injury not known, 5322-24. No considerable account of case published, 5428-31.

Prohibition of preservatives in milk should be absolute, 5220. Salicylic acid should be prohibited as a preservative, 5275-76.

Colouring matter, doubtless harmless, used in spices and pepper, 5347-49. Harmless colours not objected to in butter, cheese, confectionery, and general fancy goods, 5350, and might be allowed, 5385-87. Colouring milk might be an offence, 5351; as fraudulent, 5352, 5420-21; not so with butter, 5353-57. Unknown red dye found in jam, 5361; and red dyes found in sausages and meat, 5362, 5377-78. Unnecessary and undesirable, 5363, 5370. Injury to health and fraud not in question, 5364-66. No colouring found in cocoa, tea, coffee, 5379. Control of colourings a difficult problem, 5384. Scheduling might be adopted, 5385. Injurious colours not met with now, but Dr. Campbell Brown has found lead chromate in sugar oranges and lemons, 5387-90. Iron and oxide of iron not usually classed as poison and poisonous salts, 5394.

Copper in peas used in diminished quantity; use requires very strict control, 5337-40, 5344-46. About  $2\frac{1}{2}$  ozs. of peas examined, 5341; from well-shaken samples 5342. Has found  $\frac{1}{4}$  grain per lb. in peas quite green. Interior of peas found to contain

Précis.

Précis.

copper, 5343. Copper is injurious to health, 5367; and along with its salts, poisonous, 5393. Minute quantity suffices for peas, 5369, 5380-83. About 40 per cent. of copper in peas enters the stomach in a soluble form, 5372-76. Copper used to green the peas, 5402; and fraudulent in the abstract, 5403-5; but purchaser not prejudiced, 5406; but consumer may be, 5407-15; no doubt is, 5420-27. No injury to health from  $\frac{1}{2}$  grain per lb., 5417.

Declaration of colouring matters might prevent fraud, 5350. Should be made as to cocoa nibs coloured by red oxides of iron, 5395-5400; and of copper in peas, 5401.

Prohibition of copper in peas desired, 5358, 5416; and if not should be strictly limited, 5359. Peas probably unsaleable if not greened, 5360, 5368.

#### WILLIAMS, DR. WILLIAM. (Digest of his Evidence.)

Medical Officer of Health for the County of Glamorgan. Represents the Incorporated Society of Medical Officers of Health, 2108-10.

Boracic preservatives, 2188, 2190, especially in milk and butter, subject of action by Glamorgan County Council, 2111. Use of these preservatives utterly bad in principle, and held to have caused injury, 2112. Analyses made of vended samples of milk and butter, 2113-14. By whom preservative added in general not known; farm-dairymen added it in one instance, 2115. Addition in milk varied from  $13\frac{1}{2}$  to 210 grains per gallon, 2116, 2118. The latter unnecessarily excessive, 2117, 2121. No precise method of addition of preservative, 2119. Double addition may take place, 2120. Preservative not affected by cooking, 2124-25. Amount in butter has varied from 1 grain to 112 grains per lb., 2125; mostly imported butter, 2125\*. Boracic acid nearly tasteless, 2139. Amount used varies with the season, 2141. Most frequently used in hottest weather, 2142, and most samples taken then, 2143. Borax and boracic acid are, one the salt, one the derivative, of the other, 2231. Boracic acid inserted in solution in fish and eggs, 2232. Found in decreasing percentage of samples of food in Glamorgan, 2239.

Injury to health from preservatives cannot be proved, 2133-34, 2183-86, and not known of, 2146, but certainly may arise, 2149-51. Question of injury based on experts' statements, 2180-81. Boracic acid no doubt a poisonous drug, 2195, but failure of observation may account for absence of proof of its injury in food, 2196-98. Different modes of its administration as a drug and in food may account for difference of action on man, 2199-2200. Boracic acid contra-indicated in certain diseases, 2213.

Diarrhoea regarded as persistent by reason of use of preservatives in milk, 2171-74, 2224-25, producing ptomaines, 2191, 2191\*. No such cases known of, 2175-76, nor diarrhoea as induced by ptomaines, 2192, in milk or meat, 2193-94. Infantile diarrhoea not specially studied, 2216.

Declaration of added preservatives in milk and butter should be definite, 2140. Simple declaration would not suffice, 2147, 2152-53, 2212-14. Delivery or posting of warning notices would not be of much practical use in Glamorgan, 2154-63, save in the hands of medical men, 2164-68.

Prohibition of boron preservatives should be absolute as regards milk, 2112, 2140, 2169-70, and butter also, unless stringent rules as to quantities are passed and a minimum quantity only permitted, 2112, 2140. Prohibition of boracic acid in milk recommended by Glamorgan County Council, 2129. Convictions obtained where it was found, 2130-32, but injury to health could not be proved, 2133-34. Prohibition would curtail supply of dairy produce, 2148. It is absolute in France as to butter, if not also milk, 2218-20, save for export, 2220. Interests of dairy farmers not prejudiced by action of Council, 2221. Prohibition would effect small vendors, 2245-52, 2255-56, and might lead to monopolies, 2253, or co-operative associations, 2254.

Prosecutions have stopped use of boracic preservatives 2137, to some extent, 2138, 2144-45, 2222-23,

without prejudice to interests of dairy farmers, 2221. Formalin may have replaced boron preservatives, 2240-41.

Dose of boracic acid in Pharmacopœia 5 to 15 grains, 2204-5. Much exceeded in milk, 2206-8, especially in the case of children, 2209-11.

Milk in danger of being sold in decomposed state if preservatives are used, 2112. Partly decomposed milk most frequently preservative, 2182. Would not give preservative milk to children or invalids, 2122, who are the largest consumers, 2123. Milk requires no preservative, 2170, 2177-79, 2257-58. Preservatives would not do away with sourness of milk, 2187, but would sweeten it, 2189, borax and boracic acid being in question, 2190. Innocuous quality in decomposed milk not known of, 2201-3. Amount in Sunday milk not known, 2217. Whether partly decomposed milk better by reason of added preservative not known, 2242-44.

Butter samples, to extent of  $26\frac{1}{2}$  per cent. of number, contained preservatives in 1899, 2126. Some were of salted butter, 2127-28. Seventeen grains per lb. enough to preserve butter. Proceedings instituted by Glamorgan County Council when double that amount found, 2129. Proceedings taken and convictions obtained, 2135-36.

Ham containing 56 grains of boracic acid per lb. formed the subject of proceedings at Pontypridd, 2226-28, 2234. Acid held to be introduced in cure, 2228. Certainly used for cure, 2229, but distinction between cure by and packing in borax not drawn, 2230. Curing process not known, 2232, 2234-35, but cure could not be effected by simply dipping in a boracic acid solution, 2233. Penetrative power of borax not known, 2236. Part of particular ham yielding borax not known, 2237-38.

#### WOMACK, MR. FREDK. (Digest of his Evidence.)

Bachelor of Science, M.B., and Lecturer on Physics at St Bartholomew's Hospital and Bedford College, 7473. Nominee of St. Bartholomew's Hospital, 7480-82, 7493.

Milk preservative known in a few cases to have caused derangement, 7474; a small amount of boracic acid in milk having caused digestive disturbance in individuals, 7475-77.

Boracic acid used medicinally in large quantities has, according to Dr Church, caused digestive disturbance; not so in small quantity, 7492. Harmful doses were of 15 grains, 7494-96, every four or six hours, 7497. Not aware of 80 grains in a pint of milk, 7498, which would modify Dr. Church's opinion, 7499. Difficult to determine boracic acid quantitatively, 7521.

Prohibition absolutely of preservatives in milk and butter advocated by Mr. Lockwood, 7507.

Preservatives not strongly objected to, 7478, but regulation desirable, 7479. Antiseptics not necessarily destructive of all bacteria, 7487-88. No evidence of ill results in St. Bartholomew's wards from small doses of preservatives, 7502, 7523-24. No good results reported, 7503. Staff generally hostile to preservatives, 7504, 7508, and against their indiscriminate use in food, 7505-6.

Formalin not known from physiological point of view, 7483-84, but its indiscriminate use objected to, 7485, as interfering with digestibility of food, 7486. It might act on secreting power of cells, 7489. It is a hardening substance, 7490, and its use should be limited, 7491. Objected to by St. Bartholomew's Medical Staff in milk and butter, 7500-1. Formic aldehyde for hardening substances used in much higher proportion than as a preservative, 7513-15. The compound formed with proteids by formic aldehyde will be indigestible, 7516, and the formic aldehyde would render milk indigestible, 7517-18, and should be largely under restriction, 7519. Difficult to determine quantity present, 7520.

Salicylic acid difficult to determine quantitatively, 7522.

Colouring matters not subject of evidence by St. Bartholomew's Hospital, 7509.

Copper in any quantity likely to be highly deleterious, 7510-12.

# INDEX TO EVIDENCE.

ALPHABETICAL LIST of Headings and Sub-Headings to be found in the Index, with References to the Numbers under which they appear.

| Headings and Sub-Headings.              | Reference Number in Index. | Headings and Sub-Headings.                            | Reference Number in Index. |

### COLOURING MATTERS.

The following headings and sub-headings occur in the order here given :—

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

#### 1. AMMONIA :

Irritant in certain quantities, *Boyce*, 2753.

#### 2. ANALYSES :

Made for Crosse and Blackwell by a professional adviser, *Blackwell*, 4902-4.

Qualitative of preservatives easy, *Richmond*, 5702 ; also quantitative as to boracic acid and salicylic acid, but not formaldehyde, 5703-5 ; a volatile substance, 5706-10 ; and difficulty as to precise quantity originally present arises, 5711 ; and the strength of solution employed, 5712-14. Question of cost comes in as regards quantitative analyses, 5741.

##### 2a. BORACIC ACID :

Quantitative, difficult, but accurate, *Vasey*, 1987-90, 2036.

Quantitative, made of Birmingham milk samples, *Hill*, 2333.

No difficulty now in estimating amount in milk by a process of blank experiments, *Cassal*, 3866, 3870-71.

Quantity in food can be determined without difficulty, *W. C. Williams*, 5313-15.

Quantitative analyses, easy, *Richmond*, 5703-5. Difficult to determine precise quantity, *Dupré* 5920.

Difficult to determine boracic acid quantitatively, *Womack*, 7521.

Qualitative, easy, *Bannister*, 3554.

#### 2. ANALYSES—*continued*.

##### 2b. FORMALIN :

Quantitative determination not yet possible to witness, *Cassal*, 3837, 3866.

Might determine 1-50,000 by colour process, *Cassal*, 3867-69.

Quantitative determination not known, probably impracticable, and hence danger *quâ* use in food arises, *Foulerton*, 4142-44.

Quantitative determination accurately impracticable, *Fisher*, 4753.

Difficulty as to determining small quantities, *Stevenson*, 4830-31.

Amount in milk cannot be precisely determined, but its presence can be detected, *W. C. Williams*, 5162-63.

Difficult to determine quantity present, *Womack*, 7520.

##### 2c. SALICYLIC ACID :

Difficult to determine quantitatively, *Womack*, 7522.

#### 3. ANTHRAX :

Animals insusceptible not known, *Annett*, 2669.

Mice susceptibility known, *Annett*, 2670.

#### 4. ANTISEPTICS :

Should not be used in food, *Walford*, 1826-27.

Use increasing, *Walford*, 1828, 1853, 1921.

## 5. ARCTICANUS:

Used in milk, *Robinson*, 3309-10.  
Relation with intestinal mischief when used in milk thought of, *Robinson*, 3334.

## 6. BACON.

## 6a. ABSORBENT POWER:

None in winter, *Bennett*, 142.

## 6b. CONDITION:

To-day better than ever before, *Kellitt*, 19.

## 6c. CURE:

Salt and saltpetre used, *Kellitt*, 16.

Not effected by borax or boracic acid, *Kellitt*, 17, 20; *Gregson*, 864.

Effected before borax is used, *Kellitt*, 64.

Process described, *Bennett*, 182-84.

Mild now preferred, *Trengrouse*, 614; *Gregson*, 858, 862.

Thorough cure a matter of time in salt, *Sinclair*, 943-44.

Less prolonged than formerly, *Davidson*, 1613.

By 0.6 per cent. of boracic acid better for stomach than old salt cured, *Bell*, 2821.

Suggested to be by injection of boracic acid, *Bell*, 2822-23; Mild, by use of borax, not otherwise imported, *Bannister*, 3485-86.

Bacon of Wiltshire brand cured by Harris & Co., of Calne, *Harris*, 5951-53. Salt and saltpetre used in the cure, 5954, and these alone, 5955.

American bacon cured with salt and saltpetre, and packed in borax, and this borax washed out over here, *Harris*, 5967. Borax not used for curing in home trade, and rarely in Ireland, 5979.

Mild-cured bacon possible without the aid of borax, though perhaps nothing better known for use from America, *Harris*, 5986. It can be so produced and exported, 6007. Injection of borax in brine very seldom made, and quite unnecessary, 5987. Mild-cured bacon was possible before preservatives came in, and trade now all year round, 6002-3. It is exported to greater distances than America, and in a state fit to go to the seller, not in a green state like the American exported meat, 6008-9.

## 6d. CURE: Bacon, American:

Formerly in salt, *Kellitt*, 15.

Mild produced, *Trengrouse*, 616.

Years ago only hard-salted, *Trengrouse*, 615.

Pickle used for some, by injection, *Gregson*, 865, 902-3.

This side, after transit by refrigeration, possible, but has failed, and is costly and risky, *Gregson*, 905-8, 909-13, 921-23.

By salt and saltpetre, and packed in borax, *Harris*, 5967.

## 6e. CURE: Bacon, Danish:

Improvement on Irish mode, *Kellitt*, 75.

## 6f. CURE: Bacon, Irish:

Like Danish, 20-30 years ago, *Kellitt*, 73-74.

Mild-cured trade growing, *Gregson*, 862.

Borax rarely used, *Harris*, 5979.

## 6g. DANISH:

Formerly too salt, especially "in pocket," not so now, *Kellitt*, 21, 65-67.

A large trade, *Faber*, 4232. No present regulations as to preservatives, but prohibition intended in meat products generally, 4233, on ground of injuriousness, 4234. Borax only used, and that in limited amount, 4235, and does not penetrate from outside, 4236. Injection of solution of salt containing borax is made into the meat in curing some bacon, 4237-40. Percentages given of salt in certain Danish, Irish, Dorset, and Wiltshire bacon, 4241-42 according to which injected meat might contain 0.4 to 0.8 per cent. of borax, 4243.

## 6h. HOME:

Export trade of Harris & Co., large, *Harris*, 5956, 5988, but larger part of trade is home, 5989. Dried bacon packed in salt, 5957, in

## 6. BACON—continued.

## 6h. HOME—continued.

canvas bags in dry salt in cases for India and the Cape, 5958-59. No occasion found for borax packing, 5960. Canvas keeps out the salt, 5963. Method quite satisfactory, 5965. Bacon sent abroad is a little more salt and extra dry, 5990. Sent to India, Cape, China, &c., 5991-92, 6010, to hot climates, by steamship, 5993, probably in cool chamber, 5994. It is packed in the hold, 5995-96, and is in high temperature in many cases, 5997. No complaints received, 5998. Boracised bacon sent abroad from America by way of England, packed here again like English bacon, 6011-13.

## 6j. FRENCH:

Conditions as to presence of borax in imported bacon not altered, *Harris*, 5999; as experience has shown recently, 6000; but rather they are stricter, 6001. Temporary withdrawal not known of, 6014.

## 6k. HUNG:

And dried after borax washed off, *Kellitt*, 64. Boron used in summer, *Kellitt*, 64.

## 6l. IRISH:

Formerly too salty, especially in the "pocket," this now altered, *Kellitt*, 21, 65-67. Not preservatised, *Long*, 4658.

## 6m. PRESERVATION:

Borax only known method, *Bennett*, 171.

Methods other than borax unsuccessfully sought, *Bennett*, 171.

Borax only desired method, *Bennett*, 172.

## 6n. SMOKED:

On arrival in green state, *Hudson*, 506-8.

Would not do from America, *Harris*, 6037-38. "Smokine" known, but not used by best curers, 6039-41.

## 6o. TAINTED:

Less frequent since preservatives used, *Kellitt*, 39; obviated by them, *Gregson*, 873, 881-82.

Once marketable, and in demand, *Kellitt*, 52.

Is bacon not sweet, *Kellitt*, 53.

Obtainable, when used, at a cheap rate, *Kellitt*, 54.

Once preferred, apart from price, *Kellitt*, 55.

Caused much loss before preservatives used, *Bennett*, 188.

None now, save from negligence, *Bennett*, 188.

Not now marketable, *Bennett*, 191; *Bannister* 3497.

Seized now, *Bennett*, 191.

Related to bad or imperfect curing, *Gregson*, 916-18.

Taint not obviated in bad bacon by borax, *Gregson*, 916-18.

Occurs before complete cure, *Gregson*, 919-20. Is in interior of meat and of flavour different to borax, *Davidson*, 1608-9.

## 7. BENZOIC ACID:

Never found in butter, *Hill*, 2351.

Used in France because, and since salicylic acid detected, *Robinson*, 3311.

Found in wines, *Cassal*, 3816.

Irritating when swallowed, *Hutchison*, 6743; in 5 to 10 grain doses, 6744; on an empty stomach, 6745; in single doses daily, 6746. Frequently prescribed for septic conditions of urine, 6747. No local stomache irritation noticed when it was prescribed, 6748.

## BLANCMANGE.

(See under Milk, Boracised, Physiological effects.

## 8. BORACIC ACID:

Not a trade term, *Kellitt*, 25.

Was used by itself, but discontinued as insoluble, *Shanahan*, 348-49.

Was used in hot solution after cooling, *Shanahan*, 350.

Mixed with borax, as a preservative, *Prossor*, 561-62.

8. BORACIC ACID—*continued*.

Chief preservative, *Trenyhouse*, 617-18.  
 Superior to salt as a preservative, *Trenyhouse*, 702.  
 Not used 30 years back, *Gregson*, 858.  
 Components borax and boracic acid, *Clement*, 1529.  
 A drug, used medicinally, *Walford*, 1835.  
 A saturated solution of  $\frac{1}{30}$ , *Bell*, 2827-28.  
 Found in many vegetables, in wines, and hop plant, *Attfield*, 6550.

## 8a. CHARACTER :

Borax and boracic acid are, one the salt, one the derivative, of the other, *Williams*, 2231.

## 8b. INJECTION INTO MEAT :

Unknown, *Gregson*, 902-3.

## 8c. PRESERVATIVE PROPERTIES :

Studied, *Corfield*, 5071.  
 Service and security doubted, *W. C. Williams*, 5255, 5261.  
 Only preservative to be condoned in any way, *Hehner*, 5614, and solely in butter, in annually diminishing quantity to vanishing point, 5615.  
 As a commercial preservative contains on an average 56.8 per cent. of boric anhydride, *Richmond*, 5676-77. Not a germicide, 5742, rather an antiseptic, 5743.

## 8d. SEASONAL INFLUENCE :

Not known, *Walford*, 1851-52.

## 8e. SURGICAL USE :

Relatively harmless for external use, *Handford*, 2264.  
 Used as lotion and dressing with alleged bad results, *Handford*, 2283.  
 Studied, *Bell*, 2783-84.  
 Used largely for washing out bladder, *Bell*, 2797.  
 Fatal results following internal washing, would equally have followed use of water, *Bell*, 2799, 2800-2.  
 Inquiry held to have followed, *Robinson*, 3304.  
 Used externally, *Corfield*, 5091.

## 8f. BUTTER :

Objections made by Brazilian Government in 1891 as regards tinned butter, *Lovell*, 720.  
 Large amounts might bad flavour and partial decomposition, *Lovell*, 723, 783-89.

## 8g. EGGS :

Inserted in solution, *Williams*, 2232.

## 8h. FISH :

Inserted in solution, *Williams*, 2232.

## 8j. FOOD :

Objected to, *Long*, 4661-63.

## 8k. GAME :

Sprinkled to keep it fresh, *Hudson*, 518-19.

## 8l. MARGARINE :

Found in mixture of margarine and butter, and in margarine alone, *Cassal*, 3852.

## 8m. MEAT :

Sprinkled to keep meat fresh, *Hudson*, 518-19.  
 Not common in fresh meats; sometimes used in sausages; more commonly used in salt meats, German sausages (under  $\frac{1}{2}$  per cent.), bacon, and ham (from  $\frac{1}{3}$  to  $\frac{3}{4}$  per cent.), *Fisher*, 4717.

## 9. BORAX :

No opposition to use found, *Kellitt*, 7.

## 9a. BACON, TREATMENT OF :

In boxes; dusted on bacon to prevent fly-blow and absorb moisture, *Kellitt*, 11, 12, 15, 23.

## 9b. CANADIAN HOG PRODUCTS :

Dry borax, only, used, *Bennett*, 138, 143-44.  
 Use became general 20 years ago, *Bennett*, 232.  
 Sprinkled, 4 ozs. of dry borax to 56 lbs., during last 20 years, after cure, *Bennett*, 128-30, 184-87.  
 Borax washed off on arrival here, *Bennett*, 128-30, 184-87.

9. BORAX—*continued*.9b. CANADIAN HOG PRODUCTS—*continued*.

Washing rids meat of 80 per cent of borax, and of whole in winter, *Bennett*, 140-42.  
 Sprinkling only method known, *Bennett*, 151.  
 Noticed more than in English and Irish bacon, *Bennett*, 135.

## 9c. COST :

Expensive, six or seven cents per lb. in America, *Gregson*, 888.  
 Inexpensive for packing purposes, *Bannister*, 3488.

## 9d. HAMS, TREATMENT OF :

American, packed with borax from three to six weeks, *Kellitt*, 57, 59, 63.  
 Borax washed off by retailer, *Kellitt*, 58, 62.  
 Only method known or desired, *Bennett*, 171, 172.

## 9e. HAMS, USE ON :

Put on in packing process, *Kellitt*, 61.  
 For preserving, after cure, with salt and salt-petre, *Bannister*, 3648.

## 9f. INJECTION INTO MEAT VESSELS :

Not known, *Bennett*, 192.  
 Would flavour the meat, *Bennett*, 192.  
 In solution of salt made in curing some Danish bacon, *Faber*, 4237-40.

## 10. BORAX AND BORACIC ACID :

Difference not known, *Kellitt*, 10, 25.  
 Mixture guaranteed to contain 50 per cent. of boracic acid, *Clement*, 1530.  
 Would be surprised to learn that  $\frac{5}{8}$ ths of the mixture consisted of boracic acid, *Clement*, 1531.

## 11. BORIC GLYCERIDE :

Contains boracic acid and glycerine, and is unworkable, *Shanahan*, 347.

## 12. BORON :

Preparation of borax, but drier, *Kellitt*, 24.  
 Quick absorbent of moisture, *Kellitt*, 24.  
 Objectionable ingredient in boracic acid, *McFadyen*, 1804.  
 Boric compounds sold freely, but not in large domestic use, *Cameron*, 2531; boracic acid and glacialine the only known boric compound in Leeds, *Cameron*, 2537-38.  
 Borax and boracic compound used as preservatives, *McCracken*, 2856, 3007-9.  
 Boric compounds commonly used, *W. C. Williams*, 5148; borate found in sausages, and pork pies, 5180; boracic preservatives all mixtures, 5246-47.

## 12a. BACON, USE ON :

Hung bacon in summer, *Kellitt*, 64.

## 12b. BUTTER, USE IN :

Boric compounds found, *Cameron*, 2528.

## 13. BUTTER :

## 13a. ADULTERATED :

Most frequently preservative, *Kaye*, 5458.

## 13b. ARGENTINE :

Refrigerated butter commands high price, *Lovell*, 773.  
 Preservative, *Clement*, 1516;  $\frac{1}{2}$  per cent., *Lovell*, 774.  
 Varying quality, *Clement*, 1515.

## 13c. AUSTRALASIAN :

Australian butter known as "Colonial butter" *Clement*, 1506.

## 13d. AUSTRALASIAN : Consumption :

As a rule within a month of leaving the refrigerator, but sometimes kept for months, *Clement*, 1544-46.

## 13e. BELGIAN :

Does not keep well, *Lovell*, 766.

## 13f. COLONIAL : Borax :

Wrappers soaked in solution effective means of preserving, *Bennett*, 202-3.

## BUTTER—continued.

- 13f. COLONIAL: Borax—continued.  
Boraxed wrappers advocated, *Bennett*, 208, 214.  
No mixture, *Bennett*, 200, 201.
- 13g. COLONIAL: Supply:  
Never purchased, *Kellitt*, 49.
- 13h. CONSUMPTION:  
Now quick, *Jones*, 1342-46.
- 13j. CONTINENTAL:  
On consumer's table in three days, *Lovell*, 793-95.
- 13k. COUNTRY OF ORIGIN:  
Chiefly Danish, *Kellitt*, 44.  
Secondary qualities from Ireland, *Kellitt*, 44.
- 13l. HOT WEATHER:  
Sends butter bad in two days, *Sandes*, 118;  
and rotten in a week, *Sandes*, 120, 121.
- 13m. BUTTER-MILK:  
Expressed from Irish factory butter, *Shanahan*, 351.  
Retention militates against keeping quality of butter, *Shanahan*, 387-88.
- 13n. MILK:  
Pasteurised before creaming, to rid it of feeding taint, *Shanahan*, 449-56.
- 13o. NORMANDY: Complaints:  
None, *Hudson*, 501-2.
- 13p. PASTURE:  
Sceptical as to effect on keeping quality, *Voelcker*, 1733-34.  
May effect texture but not keeping quality, *McFadyean*, 1761-62.
- 13q. RANCIDITY:  
Caused by imperfect manufacture, *Shanahan*, 438-40.  
Rancid butters analysed without detection of preservatives, *Boseley*, 1003-4.  
Known with preservatised butter, *Jones*, 1363-64, 1378-84.  
Would kill flavour of boracic acid, *Clement*, 1541-42.  
Could not be veiled by boracic acid, *Clement*, 1543.  
Could hardly be veiled by preservatives, *Voelcker*, 1714.
- 13r. SCANDINAVIAN:  
Sometimes preservatised, *Lovell*, 752-54.  
Only small export from Norway, *Lovell*, 756-57.  
Export of Finnish butter exceeds that of Norwegian, *Lovell*, 757.
- 13s. SCOTCH:  
"Fresh" butter is saltless and unpreservatised, *McCracken*, 2861.  
Used day by day, *McCracken*, 2938-39.
- 13t. SOIL:  
Important in relation to keeping quality of butter, *Shanahan*, 420-37; *Lovell*, 772.
- 13v. SUPPLY:  
In Newport (Mon.), local, Irish, and Danish, *Jones*, 1400.  
To Birmingham largely local in summer, and continental in winter, *Hill*, 2472, 2474.
- 13w. DANISH: Supply:  
Chief, *Kellitt*, 44.  
Increasing in England owing to improved methods of manufacture, *Dale*, 260-62.  
Sale probably decreasing, *Hudson*, 538-40;  
replaced in good firms during winter by Colonial and Irish, *Hudson*, 541.  
Bulk of English trade, *Trengrouse*, 683-85, 693.  
Used chiefly by middle class, *Trengrouse*, 698.  
Decreasing demand because of pasteurisation, *Lovell*, 730.  
No difficulty of vending, *Hehner*, 5603.

## BUTTER—continued.

- 13x. IRISH: Supply:  
For English market expressly, *Sandes*, 113.  
Turns out a ton a week, *Sandes*, 123.  
Much shipped on chance of sale, *Dale*, 301.  
Much goes to London, *Dale*, 303-5.
- 13y. UNIFORMITY:  
Demanded, *Dale*, 241-42, and secured, *Dale*, 245.
- 13z. WINTER:  
Very little salt, less made, *Sandes*, 105.  
Quality not so good as grass butter, *Sandes*, 105.
14. CATTLE FOOD CAKES:  
Test samples contained borax purposely added, in cotton cake one lb. to a ton, to preserve colour. It might cover inferior make, and excess of mixture might lead to fermentative change. Such preservatised cake has not been adopted. Borax or formalin not used in the trade, *Voelcker*, 1687-90, 1709-11.
15. CHEESE:  
Skim milk made into, in summer, *McCracken*, 2910.
16. CLEANLINESS:
- 16a. BUTTER, IRISH:  
Not enforced at nor proper inspection made of Irish farms: and creameries also need looking to, *Gibson*, 6404.  
Water supply to farms not looked to, 6678; but supply is good in North Ireland, *Lough*, 6679.
- 16b. MILK:  
Essential to the keeping of milk, *Long*, 4578.  
Four ounces of slime taken by heavy milk drinker per annum, *Long*, 4579, 4694-95.  
Dirt masked by preservatives, *Long*, 4671, 4695; which put a premium on good dairying, 4677.  
Absolute necessity, on which preservatives put a premium, *Tubb-Thomas*, 4936-38, 5027-32, 5039-40.  
Of milk churns ensured by treatment by Aylesbury Dairy Co. before return to farmers, *Hattersley*, 5786.  
Contracts of Manchester Pure Milk Supply Co. very stringent with farmers, and milk cans cleansed before return, *Sorensen*, 7060; and farm water supply looked to, 7061-63; and cooking of milk to 40 degrees insisted on, 7064; as requisite to a daily delivery, 7139-40. Price none the less lower than average vendor, 7064, 7158-60, and footnote. Milk is received in sealed churns, 7076-79.
- 16c. MILK, PRESERVATISED:  
At a premium, *Jones*, 1309, 1362, 1365.  
Preservatives predispose to lack of cleanliness and sanitary precautions, *McFadyean*, 1753.  
Dirt, putrefaction, and infective quality of milk concealed, *Robinson*, 3312.  
Desirable to prevent bacterial activity by early addition of preservative, if allowed, *Foulerton*, 4053-57.  
Preservatives put a premium on cleanliness, *W. C. Williams*, 5306-7.  
Preservatives may enable cleanliness in milk trade to be dispensed with, *Brunton*, 7430.
- 16d. PRESERVATIVES:  
Use does not counterbalance uncleanness; any premium placed on cleanliness to be deprecated, *Foulerton*, 4113-14, 4137.  
Likely to lead to neglect of cleanliness, *Corfield*, 5113.  
Cleanliness at a discount by their use, *Kaye*, 5454.  
Cloak for dirt, *Kaye*, 5519-20.  
Cleanliness may be discounted by their use in milk, *Dupré*, 5902-3. Guarantee of cleanliness lost when preservatives added to milk, 5905. Indeed, dirt is cloaked by such addition, 5942-47.

6. CLEANLINESS—*continued*.16d. PRESERVATIVES—*continued*.

Uncleanliness of dairies arising from use of preservatives should be met by inspection, *Hutchison*, 6767.

Food preservatives may be dirty and contaminated and yet sterile, *Hope*, 6867-69.

## 17. COLD :

17a. A better preservative than drugs or minerals, *Hill*, 2500-1 ;

Preserving of food to be desired and waste prevented, *Hope*, 6822-23. Cold storage and chemical preservatives, two known means of preserving food, 6824. Copenhagen system of cold storage, 6624 ; not applicable here by reason of cost of ice and cost of inauguration, 6825. System failed in Liverpool ; doubtless it has had some success in Manchester, 6826. The Copenhagen plan is worked by block ice, 6827.

Limited application will keep milk sweet for some time, *Hope*, 6828.

Cold storage to be preferred to preservatives for food, *Halliburton*, 7530-32.

## 17b. BUTTER : Cold Store :

Used for overstock, *Hudson*, 548.

Butter never spoils, *Hudson*, 548.

In vogue for past five years, *Hudson*, 553.

## 17c. BUTTER, AUSTRALASIAN : Cold Storage :

Keeps it fresh and sweet, *Hudson*, 504.

Largely brought over, *Trengrouse*, 620, 623.

Used for stock more than a week old, *Trengrouse*, 665.

Keeps butter for nine months in full flavour with  $\frac{1}{2}$  per cent. of preservative, *Lovell*, 727.

Demands preservatives to prevent spoiling the defrosted butter, *Lovell*, 776, 778-81.

Used on arrival, *Lovell*, 802.

New Zealand butter comes in cold chambers with some salt, *Riley*, 830-1, 833.

Used for Australian butter, *Hill*, 2478.

## 17d. BUTTER, IRISH : Cooling :

Cold storage non-existent in Ireland, *Gibson*, 6379 ; and price of ice there prohibitory of refrigerating plant for general use, 6380-84. Creameries have cooling tanks, not so the farms, 6401, and the milk travels long before cooling is accomplished, 6402-3.

## 17e. MILK : Cold Storage :

Suffices in place of preservatives, *Cassal*, 3804.

Necessary in very hot weather, and possible for small traders, *Cassal*, 3807-8, 3862.

Will keep milk fresh for some considerable time, say milk cooled to 40 degrees, *De Hailes*, 3917, 3950 ; many farms cannot cool to below 60 degrees, 3917. Many farmers have not got cold water, 3918-21, 3951-56. Some of London milk trade does not use preservative, 3922. Preservatives the only cheap method of safeguarding milk in view of absence of cold water at many farms, 3957-63. Cold storage would render preservatives in milk unnecessary to large communities, 4010 ; not so cooling of the milk, 4011. Aylesbury Dairy Co.'s procedure not known, 4012-15. Cold storage milk vendors are against the use of preservatives, 4031.

## 17f. MILK : Cooling :

Would suffice immediately after milking under all ordinary circumstances, *Cassal*, 3862.

Essential, *Carrington-Smith*, 4431. Apparatus of cold water tubing used, 4432. Some farmers do not command the needed water supply 4433 ; which is necessary to long distance milk transit, 4434. Cooling chambers should be used by the consignees, 4434-35. Railway vans should be such as to keep the milk cool, down to 60° F., 4435-39. Cooling of milk plus cleanliness keeps milk sweet during transit, 4504. Witness sieves milk three or four times and is particular as to cleanliness of cattle and sheds, 4505 ; and these have their effect on keeping power of

17. COLD—*continued*.17f. MILK : Cooling—*continued*.

milk, but cooling the most important factor, 4505. No difficulty in the way of all milk being sieved, 4507-14 ; but difficult to get it done, 4516. All dairy farmers ought to have a good water supply, 4517-20. Dairies, &c., Order ought to be enforced, 4526-27, 4531. Drought at times a difficulty as to water supply, 4528-30. Only cool water needed for refrigerating, 4531-34 ; even catch water suffices for witness, 4535-37 ; milk not coming in contact with it, 4538.

Cooling of milk well enables it to be kept 24 to 36 hours in hottest weather, *Carrington-Smith*, 4577 ; that is, cooled below 60° F., 4578. Milk kept at 60° F. for first 12 hours will keep 36 hours in all in hottest weather, 4582-84. Milk cooled from 55° to 60° F. kept 36 to 48 hours, being scalded in sultry weather, 4588-93. Imperfect cooling has led to return of milk to witness, 4611.

Should be effected, *Tubb-Thomas*, 5039-40.

Increasing in West Riding, *Kaye*, 5521-23.

On milking insisted on, by Aylesbury Dairy Company, *Hattersley*, 5781 ; as essential to its keeping, 5782, 5821-24 ; also straining, 5819. Water supply of farms traded with looked to as proper, 5827-31 ; also the sanitary condition of the farm, 5730, 5882-83, 5899-900. Cooling of milk only at fault once in 1899, 5732-34.

Cooling is relatively expensive, requiring ice, *Sorensen*, 7037 ; a commodity more easily obtainable here than is imagined, 7038 40 ; though difficulty may occur in parts, 7136-38. Ice preserved by stacking, 7041-42. Manchester supply from places comparatively near at hand, 7054-58. Milk sufficiently cool will travel 200 miles equally as well as 50 miles, 7058.

Cooling of milk, and storage at moderate temperature, of vast importance in relation with keeping power of milk, *Schidrowitz*, 7233 ; and would obviate need for preservatives, 7234. Lactic acid bacteria less resistant to preservatives than other bacteria, 7245-46. Should be enforced by Statute, 7235-37 ; under adequate inspection, 7238, 7242-44 ; though difficulty might arise as to enforcement, 7239-41. Initial cooling would allow of transit without material raising of temperature of milk, 7250 ; but refrigerator cars would be a great help, 7251. For cooling, 15° C. regarded as practically best, 7233, 7237, 7252-55. Maximum temperature of experimental milk in transit, uncooled, was 29.5° C., 7256-59 ; in milk cooled to 10.5° C., it was 1° C., 7260-61.

Cooling and sterilising would obviate need for preservatives probably, *Bruntton*, 7444. Cooling the best known form of preserving milk, 7449-51. No bad results known or feared from refrigerated milk, 7452-55.

## 17g. REFRIGERATION :

Used, it may be, at times for preservatives milk, *Brierley*, 3181.

More expensive than borax packing for bacon, *Bannister*, 3488-94.

This and sterilisation proper methods of food preservation, though perhaps more expensive, *Cassal*, 3816.

Freezing of milk might cause infantile scurvy, *Still*, 6801 ; moderate cooling would not, 6802.

Not needed for large towns, *Hope*, 6897.

## 17h. REFRIGERATION : Bacon, American :

Unsatisfactory, *Sinclair*, 936-37.

## 17j. REFRIGERATION : Butter :

Butter keeps best if preservative also added, *Snamahan*, 381-84.

Does not keep butter like butter only preservatives, *Clement*, 1508-10, 1546-47.

May serve to make kept butter dangerous *Clement*, 1547-51.

Butter decomposes readily on defrosting, *Bannister*, 3626-27.

## 18. CONTRA-INDICATION OF PRESERVATIVES:

## 18a. BORACIC ACID:

In kidney troubles, *Wild*, 1429; with albuminuria, *Wild*, 1447-50.

In numerous persons, *Wild*, 1450-52, 1455-57.

In certain conditions of stomach, especially of digestive organs of children, *Wild*, 1467-72.

No practical experience as to pregnancy, *Wild*, 1473-78.

In scarlet fever, with kidney disease, *Wild*, 1496-98.

Not in small amount in milk in enteric fever, *Wild*, 1496.

In many conditions, *Walford*, 1879-81.

In pregnancy, *Walford*, 1882, 1884-85; action on uterus unknown, *Handford*, 2294; in pregnancy not known, but not disbelieved, *Bond*, 3157-62.

In certain diseases, *Williams*, 2213.

In nephritis, *Handford*, 2292-93.

In fever, and always unless direct benefit expected, *Handford*, 2302-4.

May be administered in all conditions, *Bell*, 2808-10.

In kidney disease, in large doses, *Bond*, 3084, 3098.

For irritable stomach, *Bond*, 3135-37, 3140-42.

No wide prevalence of contra-indications, save, as to indigestion, *Bond*, 3144-46, 3148-54, 3156.

Fatal termination of kidney disease might be hastened by indiscriminate use, *Bond*, 3147, 3150, 3155.

All renal disease cases do not contra-indicate use, *Bond*, 3163.

Physician should know if milk boracised in cases of albuminuria, *Bond*, 3164-66.

Commonly in milk, including healthy persons, *Foulerton*, 4149-50.

In typhoid fever and acute nephritis, of heavily boracised milk. Injury to individuals may result from indiscriminate use of boracic acid, *Stevenson*, 4310.

Infants relatively more susceptible than adults, *Stevenson*, 4848-50.

Of borax in kidney disease not a matter on which would like to express opinion, *Hutchison*, 6705. Effect on diseased kidney thought of as small, 6707. No information on the point, 6708. No specific effect in pregnancy known, 6709-11.

Boracic acid contra-indicated and dangerous in any lesion or disease of intestinal tract, *Starling*, 6973. Dangerous to feed a typhoid patient on milk containing 20 grains of boracic acid per pint, 6974, or a diphtheria patient; both would take much milk, 6975-76.

The acid is an irritant, and therefore bad in typhoid fever, *Anderson*, 7190. It is a very feeble antiseptic, 7191. Contra-indication of boracic acid in fevers, 7205-6; and in all disorders entailing milk diet, 7208. Would not give the acid in nephritis, 7209.

Of borax in pregnancy, *Brunton*, 7463.

## 18b. FORMALDEHYDE:

Commonly in milk, including healthy persons, *Foulerton*, 4149-50.

Infants relatively more susceptible than adults, *Stevenson*, 4848-50.

## 18c. SALICYLIC ACID:

Kidney disease, *Bond*, 3108.

In large number of persons, *Corfield*, 5104-12.

Of salicylic acid in cardiac affections, *Hutchison*, 6737, and perhaps in acute nephritis, 6738. Probably dangerous in acute forms only of kidney disease, 6739.

Of salicylic acid in cardiac weakness, *Starling*, 6971, 6971.\* Its indiscriminate use objected to, 6972.

Indiscriminate use should not be permitted *Brunton*, 7464.

## 19. COOKING:

## 19a. BORACIC ACID:

Would not alter it, *Walford*, 1907-8.

Would equably distribute it in milk, *Handford*, 2274.

## 19b. FORMALIN:

Would alter it in food, *Walford*, 1918.

## 19c. PRESERVATIVES IN FOOD:

Does not affect, *Williams*, 2124-25.

## 20. COST OF PRESERVATIVES:

Greater than salt, *Dale*, 252-54, 283. Infinitesimal per lb. of butter, 284-86.

## 21. COURT OF REFERENCE:

Needed as to colourings and preservatives, *Blyth* 3407-9.

Standing committee generally agreed upon as being useful, *Blyth*, 3410.

Would be valuable as to both preservatives and colouring matters, *Stevenson*, 4851-53.

Advocated, with specific declaration of preservatives as a basis of action as to legalisation of such preservatives, *Brunton*, 7437-38. Medical profession should be well represented on such a Board, especially the Royal College of Physicians, 7439. Board originally suggested by analysts, 7440; and analysts requisite to its constitution, 7441. Such a Board would result in the formulation of definite rules as to preservatives, 7443. Our present knowledge as to milk trade without preservatives, a case in point of present defective information, 7444; as also in regard of sterilisation of milk, 7445. The Board suggested might lead to the prohibition of preservatives, 7467.

## 22. CREAM:

Increasingly in use for infants and invalids, *Handford*, 2278.

Liable to change, *Bell*, 2838.

Medical men now prescribe, in place of cod liver oil, *Cassal*, 3820.

Keeps three days without preservative, *De Hailes*, 4034, 4036.

Potted cream, for trade purposes, should keep a fortnight, *De Hailes*, 4035.

More likely to sour than milk, but point not personally vouched for, *Carrington-Smith*, 4447-53.

## 23. CREAMERIES:

## 23a. BUTTER, IRISH:

Danish style general, *Dale*, 246.

Danish style in some, *Shanahan*, 488.

Preservatives not added by creamery suppliers, *Shanahan*, 486.

Greatly improved, *Shanahan*, 387-88.

Supplied once or twice a week, *Shanahan*, 457-59, 485.

Creamery butter about one-seventh of Irish trade, *Gibson*, 6368-69.

## 23b. CREAMERIES, IRISH:

Early one started in 1885 for butter making, *Sandes*, 77, 78.

Creamery industry revolutionised of late years in Ireland, *Lough*, 6618; and very largely increased, 6619-20. Farmer waits for the separated milk, 6623; for feeding calves, 6624. Cleanliness is observed at the creameries as to milkers, cattle, utensils, storage of milk, and so on, 6677. Straining is insisted on, 6680.

## 23c. MILK FOR CREAMERY: Source of Supply:

Local, three miles distant at most, *Sandes*, 125.

## 24. CUMULATIVE PROPERTIES:

## 24a. BORACIC ACID:

Effect of doses cumulative, *Wild*, 1427.

Nil, *Bell*, 2826.

Disproved by Liebrich, pointed to by others, continued dosage tends to harm, *Blyth* 3469-71.

## 24. CUMULATIVE PROPERTIES--continued.

## 24a. BORACIC ACID--continued.

In healthy cases no cumulative effects of boracic acid, *Starling*, 6977.  
Element of uncertainty, *Brunton*, 7434-36.

## 24b. PRESERVATIVES :

Of preservatives, such as boracic acid, elements of uncertainty, *Brunton*, 7434-36.

## 25. DECLARATION :

## 25a. BORACIC ACID (SIMPLE) :

Important and sufficient as to milk, *Wild*, 1436, 1444-46, 1453-55, 1488-92.  
Would be useful to medical men, and lessen the sale of boracised milk, *Cameron*, 2581-82.  
Not necessary in regard of food, and objected to, *Bell*, 2793, 2831-33.  
Medical men should know if their patients are taking boracised food, *Blyth*, 3473.  
Should be made, *Harris*, 6035; and would do away with present injustice to English bacon trade, 6036.  
Borax should be notified, *Halliburton*, 7542-43.

## 25b. BORACIC ACID (SPECIFIC) :

Label desirable as to milk if possible, *Wild*, 1493-95; but would be difficult as to quantity, *Cameron*, 2580.  
Nature and amount should be stated, *Bond* 3095-96, 3101, 3142

## 25c. MILK, BORACISED :

Impracticable, *Handford*, 2275.

## 25d. PRESERVATIVES :

Should be made as to food, *Walford*, 1836; and would be useful as to coppered foods, *Cameron*, 2557, 2578.  
Would not suffice, *Walford*, 1837, 1870-71.  
Would suffice; but not where boracic acid is contra-indicated, *Vasey*, 2067-74.  
If preservatives found to be injurious, should be made, *McCracken*, 3005-6.  
Would not be objectionable, *Dunn*, 3019-20.  
Proper course, *Bond*, 3075, 3167.  
Fraught with difficulty as to milk, but might check amount used, *Brierley*, 3183-87.  
Should be obligatory, *Robinson*, 3312.  
Should be made; would safeguard food from repeated dosage; is preferable to labelling, *Blyth*, 3458-59, 3474-75.  
Not objected to, *Bannister*, 3677.  
Of composition of an article, should be made, *Cassal*, 3794; and compulsorily demanded if preservatives deemed necessary to cheapness of commodities, 3802; and should include nature and amount, 3858; and their probable effect, 3859-61; but less desired than prohibition, 3875. Practical difficulties in way of amounts being stated, 3878; and in precise determination of these amounts analytically, 3879-81; especially if a limiting value were insisted on, 3882-85; as to boracic acid, 3886; and more so as to formalin, 3887-98.  
Should be made, if they are permitted, *Faber*, 4203-4.  
Saccharine in wines and beer allowed in Denmark, only if declared on label, *Faber*, 4206.  
The alternative to prohibition of preservatives; it would meet the case of idiosyncratic people, *Halliburton*, 7532-33. Borax should be notified, 7542; important to the public generally, 7543.

## 25e. PRESERVATIVES IN BUTTER :

Not objected to, *Clement*, 1554-55; not necessary, 1557-59; not objected to, *Gibson*, 6352.  
Simple declaration would not suffice, *McFady-yeau*, 1759; *Williams*, 2147, 2152-53, 2212-14.  
Should be definite, *Williams*, 2140.

## 25f. PRESERVATIVES IN CREAM :

Should be obligatory, *Voelcker*, 1716, 1749.  
The alternative to prohibition, *Voelcker*, 1749.

## DECLARATION--continued.

## 25g. PRESERVATIVES IN FOOD :

Of articles as preservatised should be made, if preservatives allowed, *Long*, 4689.  
Of preservatives should be made in some cases, *Fisher*, 4726; as in milk if permitted, 4728. No resolution passed by Society of Public Analysts, 4744. Declaration of milk as formaldehysed would not guarantee against a harmful dose, 4761.  
Of preservatives should be made, *Blackwell*, 4874, 4897, and nature, 4899; and amount, 4900.  
Of preservatives not desirable, rather to be avoided, *Tubb-Thomas*, 4949; and not sufficient *quit* children and invalids, 5017-20.  
Of butter as preservatised not objected to, but country of origin might suffice, *Cameron*, 6211-13, 6243-46.  
Advisable, *Grünbaum*, 6480.  
Of preservatives not objected to if and so far as practicable, *Attfield*, 6547.  
Of preservatives, amount and nature and date of addition should be made in all cases, *Hope*, 6867.  
Should be made of pasteurisation equally with preservatisation, *Poore*, 7367. All preservatives should be declared, 7377-79, 7381-82, 7386-89, 7391; and the amount of salt, 7380. No difficulty felt as to labelling, 7390.

## 25h. PRESERVATIVES IN MILK :

Should be obligatory, *Voelcker*, 1716, 1749.  
Should be definite, *Williams*, 2140.  
Simple, would not suffice, *Williams*, 2147, 2152-53, 2212-14.  
Warning notices circulated or posted would not avail much in Co. Glamorgan, *Williams*, 2154-68.  
As to quantity, as indeed in all foods, should be made, *Hill*, 2522.  
Not impracticable, and would solve many difficulties, with no great onus on local authority, *Boyce*, 2764-68.  
Components of mixture should be declared, *Boyce*, 2770, 2773, 2776.  
Not objected to, *Bannister*, 3549.  
Difficult as to amount for several reasons, *Bannister*, 3550-53, 3558, 3628-30.  
Would tend to limit amount used, *Bannister*, 3556.  
Would not obviate risks attending partial admixtures, *Bannister*, 3635.  
Eighty grains per pint should be declared, *Bannister*, 3639.  
Should be made, *Rideal*, 3693.  
Of preservatives in milk impossible and objected to, *De Hailes*, 3932-35. Not aware of system in United States, 3936-37; and notice to all customers impracticable, 3938, as also with butter, 3941-43. Labelling impracticable, 4001; and if declaration were alternative to prohibition, the latter would have to be enforced, 4002.  
Should be made of preservatives in milk, to safeguard infants and invalids, *Foulerton*, 4047. Desirable from public health point of view, 4065. Trade interests should not stand in the way, 4066. Exact nature or amount need not be declared if officially fixed, 4067. Declaration favoured rather than prohibition, 4076.

## 25j. SALICYLIC ACID :

Should be made of nature and amount, *Bond*, 3109.  
Would like to know when he was taking it, *Robinson*, 3341.  
Of salicylic acid a matter of importance to patients taking it as a drug, *Brunton*, 7464.  
Amount should be stated, 7470.

## 26. DECOMPOSITION OF FOOD :

## 26a. BORACIC ACID :

May be concealed thereby, *Walford*, 1846; and disguised in milk, *Handford*, 2278.  
Danger from use of boracised fish unfit for sale, *Handford*, 2278.  
Abnormal decomposition prevented by 10 to 15 grains thrice daily, *Attfield*, 6497.

26. DECOMPOSITION OF FOOD—*continued*.

## 26b. BUTTER: Preservatised:

Putrefaction not arrested thereby, *Shanahan*, 483-84.

## 26c. PUTREFACTION OF FOOD:

Ill-effects caused, *Jones*, 1328-30, 1336.

## 26d. MILK:

Innocuous quality not known, *Williams*, 2201-3.

Whether partly decomposed milk better by reason of preservatives not known, *Williams*, 2242-44.

Danger would arise in the case of old milk preservatised, *Hill*, 2409.

Incipient harmful changes not perceptible to taste or smell, *Hill*, 2467-69.

Acidity as a full indication, not known, *Annett*, 2683-84.

Arrested only by pasteurisation, *Bell*, 2841.

Danger, *quid* infantile mortality, diarrhoea, and wasting, *Bannister*, 3654-55.

Acidity of milk and organic growth rapidly take place, *Rideal*, 3698.

## 26e. MILK: Boracised:

Sourness not done away with, *Williams*, 2187-90.

Putrid milk more harmful than if sweet and moderately boracised; but such putrid milk would not be purchased, *Handford*, 2306.

Putridity would be checked and veiled by boracic acid, *Handford*, 2307-8, 2319.

Injurious products may be formed, *Mann*, 2605, 2612.

Veiling, unlikely, *Annett*, 2686-88.

## 26f. MILK: Preservatised:

Does happen, *Voelcker*, 1698-1701.

When commenced could hardly be veiled by preservatives, *Voelcker*, 1712-13.

Milk a good ground for bacterial growth, *McFadyean*, 1761.

Not found, *Walford*, 1914.

Danger of decomposed milk being sold if preservatised, *Williams*, 2112.

Partly decomposed milk most frequently preservatised, *Williams*, 2182.

Lactic changes retarded, and others not retarded by preservatives, *Brierley*, 3253-54.

Preservatives not thought of as likely to veil decomposition in milk, *Hutchison*, 6717-18.

Sterility of milk claimed as regards milk rendered sterile by chemical preservatives, a false claim, *Hope*, 6870-75.

## 26g. MILK: Sour:

Slightly, is drunk by people, *Hill*, 2471.

Injurious to infants, *Annett*, 2685.

Probably more harmful than boracised milk, *Bannister*, 3546.

Danger, *quid* infantile mortality, diarrhoea and wasting, *Bannister*, 3654-55.

Change of milk detected by taste and smell, *Foulerton*, 4092-95.

Exact composition of sour milk not known, *Foulerton*, 4096-98.

Lactic change not due to any one bacillus, though lactic acid primarily in question; no taste could discriminate below 0.4 per cent. of lactic acid, *Foulerton*, 4099-4106, 4182-84.

Sourness of milk the essential test of its injuriousness, *Blaxall*, 6102-6; but a poor test of other changes going on in milk, 6137; but smell distinguishes nearly all harmful lactic changes, 6138-39.

## 27. DIARRHOEA:

Most prevalent during hot months, when preservatives presumably most in use, *Walford*, 1890-92.

Poor people most liable to, and also to get boracised milk, *Hill*, 2377-80.

Several causes can always be found, *Hill*, 2444.

Increases in the ratio of poverty, and among the class getting most preservatised milk, *Hill*, 2450-51.

27. DIARRHOEA—*continued*.

Increasingly prevalent in Leeds, despite measures adopted; most prevalent in autumn, when preservatised milk most used, chiefly by poorer classes, *Cameron*, 2539, 2574-76, 2586.

Association with preservatives not known, *Corfield*, 5128-32.

Moderate use of preservatives to be thought of as lessening risk of diarrhoea by bad milk, *Hutchison*, 6769. Diarrhoea not attributed to boracic acid in milk, 6770, rather to lack of sufficient preservative to keep milk from going bad, 6771. All diarrhoea in children not due to bad milk, 6772-73. Diarrhoea should be decreasing by use of preservatives, 6782. Not known if it be so, 6783.

## 27a. BORACIC ACID.

Results from 120 grains taken in four hours, *Wild*, 1418.

In certain children taking  $7\frac{1}{2}$  grains per pint of milk, *Wild*, 1480.

Probably kept up by boracised milk, *Walford*, 1889-93.

In a child, held to be related to boracised milk, *Handford*, 2267-73, 2314-15.

Relationship thought of, but not studied or traced; investigation a matter of difficulty, *Hill*, 2374-76, 2445-49.

Diarrhoea in children found to get worse when treated with 1 to 5 grains of boracic acid in their food, *Tubb-Thomas*, 4926, in Newport (Mon.), 4927, an industrial town. The milk ordinarily taken by the children containing from 40 to 120 and more grains of boracic acid per gallon, 2928, as ascertained by analysis and by the word of the milk vendors, 4929, who added the acid under a fancy name, 4930. Many children in question, 5001, at all seasons, 5050, for 12 months, 5051, in one locality, 5002; no multiple attacks in houses, 5003. Milk drinkers alone attacked, 5004, 5008, and all milk from one source, 5005, 5007, which hit all children alike, 5006. Other similar experiences had, 5052-54. Diarrhoea rate among children thought of as influenced by preservatives, 5009-10. The disease induced in phthisical persons on boracised-milk diet, 5024-25. Doubtless the experience recorded above regarded as exceptional because of want of knowledge on part of medical profession, 5055-56. Boracic acid, salicylic acid, formic aldehyde prescribed by witness for diarrhoea and indigestion, 5056, but not since above experience, 5058, as no control can be had over the doses taken, 5059-61.

## 27b. DIET:

Milk diet and diarrhoea closely related, *Walford*, 1897.

## 27c. INFANTILE:

Not specially studied, *Williams*, 2216.

Mortality of infants in third quarter of the year put down in part to large use of preservatised milk during the hot months, *Kaye*, 5466-72. Infantile diarrhoea mortality always excessive in third quarter, 5474-76, 5481, and preservatised milk thought of as a factor in preventing fall in such third quarter mortality, 5477-78, 5484, but some improvement to be looked for as regards towns purveying unpreservatised milk if thesis be true, 5485-88; but some cause operating prior to use of preservatives, 5482-83, and perhaps decomposed milk, 5484, 5492. Diarrhoea may be produced by changes in milk resulting from contained preservatives, 5493-94. Tinned milks not regarded as a prime factor, 5535-37, but they play their part, 5538-42. Diarrhoea caused by borax administered as a drug to children, 5503-4. Dosage not known, 5505. Conditions surrounding child-life tend to diarrhoea specially in the third quarter, 5543-46. Boracic acid a greater cause than *tabes mesenterica*, 5553-56. Diarrhoea mortality curves of Continental cities vending unpreservatised milk tend to show lower infantile rate, 5557-58.

27. DIARRHŒA—*continued*.27c. INFANTILE—*continued*.

Milk well cared for in Great Ormond Street Hospital, but two epidemics of diarrhœa definitely traced to bad milk there in summer, *Still*, 6790.

In relation with preservatives, not traced, *Hope*, 6922.

## 27d. MILK, BORACISED :

Some suspicion attaches to boracised milk, *Cameron*, 2539, 2573, 2577, 2585; *Mann*, 2605-7, 2628; *Robinson*, 3332-34.

## 27e. MILK, PRESERVATISED :

Regarded as persistent by reason of preservative milk, but cases not known of, *Williams*, 2171-76, 2191-92, 2224-25.

Diarrhœa mortality in infants probably related to preservative milk, *Annett*, 2675-80.

Some diarrhœa doubtless due thereto, *Barnister*, 3655-57.

## 27f. SANITATION :

Ought to have reduced mortality beyond its present rate, *Walford*, 1895-96.

## 28. DOSES :

## 28a. BORACIC ACID :

Personally 10-grain doses have no effect, *Wild*, 1416-17.

Doses of 15 to 20 grains not injurious singly, *Wild*, 1417.

Daily doses for a week of 15 to 20 grains create slight disturbances, which cease on omission of the acid, *Wild*, 1418.

In health and sickness, from 10 to 80 grains a day found to be beneficial, *Wild*, 1421.

In  $\frac{1}{10}$  in milk, baby would get a large hurtful dose daily, *Wild*, 1430-35; might get an over-dose, *Robinson*, 3338.

In  $\frac{1}{10}$  would be 9 grains per pint of milk, *Wild*, 1433.

For a child some three grains, *Walford*, 1876.

Sixty grains in food, and the same medicinally daily, objectionable for an adult, and a danger, *Walford*, 1877-78.

Much exceeded in milk, especially for children, *Williams*, 2206-11.

From 5 to 15 grains in Pharmacopœia, *Williams*, 2204-5.

From 10 to 15 grains, adult, and 1 to  $\frac{1}{10}$  grain, infant, *Handford*, 2270.

More than a maximum dose might be taken in food in a day in Birmingham by a patient taking also a medicinal dose, *Hill*, 2458-59.

Infants might take a full dose in milk, *Cameron*, 2536.

Reason for reduction in Pharmacopœia not known, *Bell*, 2803-4.

Ten grains suffice to produce a medicinal effect, that is, 30 grains a day, *Bell*, 2805-7.

Fifty grains absurd and unnecessary for an adult, *Bell*, 2813, 2815.

Would not give a child 40 grains, *Bell*, 2816.

Ten grains given to hundreds of patients, *Bond*, 3064.

Usually 30 grains per diem, *Bond*, 3066.

Gives grain doses to children in diarrhœa, *Bond*, 3071, 3073.

Child, one-fifth that of an adult, *Bond*, 3076-78.

From two to three grains for child of five years, but more not dangerous, *Bond*, 3080-81.

Forty grains a day limit for adult, *Bond*, 3079.

Danger limit unknown, *Bond*, 3082.

Child might take too large a dose in milk, *Bond*, 3090-93; in  $\frac{1}{10}$ , *Robinson*, 3338.

Experiments by large dosage of individuals, discounted by idiosyncrasy, *Robinson*, 3339.

No one should have more than 15 grains daily under any circumstances, *Stevenson*, 4834-36.

Reduced 50 per cent. in new edition of Pharmacopœia, *Tubb-Thomas*, 5062; *Corfield*, 5090.

Probably only a certain quantity can be voided daily, and any larger dosage undesirable, *Corfield*, 5075, 5080.

28. DOSES—*continued*.28a. BORACIC ACID—*continued*.

Over dosage likely, *Corfield*, 5082.

Boracic acid taken, from 10 to 15 grains thrice daily, as sufficing to prevent abnormal stomachic decomposition of food, *Attfield*, 6497; but larger doses have been taken, though 10 grains found sufficient, 6497-98. As much as 70 grains daily taken experimentally, 6499. No inconvenience resulted, 6500.

Reduced in Pharmacopœia because present dosage produces all needed effects, *Attfield*, 6533-35, and larger doses do no more, 6536. Has taken 100 grains in one day, 6537; and has kept up 45 grains daily for weeks, 6538. Desirable to know the quantity of boracic acid being taken with food, 6557; but matter not of great importance, 6558-59.

Would not like to take 80 grains as a dose, 6713; even with a pint of milk, *Hutchison*, 6714.

## 28b. SALICYLIC ACID :

Usually 30 grains daily, *Bond*, 3130-31.

Salicylic acid may be taken from 5 to 15 grains at a time, without retarding digestion, *Attfield*, 6568.

## 29. DRUGS :

Not defined by statute in relation to foods, *Cassal*, 3789-94.

Substance of a poisonous character, or having active character as a drug, should not be used in food, *Cassal*, 3794.

Objectionable as preservatives, *Hehner*, 5637-38.

## 30. EGG POWDERS :

Egg powders are baking powders, one such powder is prepared with dried egg, *Hope*, 6853; some are not egg powders at all, yet are used by some persons as food for children, 6854, 6859-62. Some labelled as not made from eggs, 6855; as the result of a prosecution, 6856-58. Powders are coloured to simulate egg-colouring, 6863, 6865-66. Egg powders looked upon by vendors as naturally eggless, 6864.

## 31. EXPERIMENTS :

In and outside human body not on the same plane, *Cassal*, 3872.

Home Office licence necessary in the case of animals, *Stevenson*, 4820.

Evidence not decisive nor satisfactory thus far, *Tubb-Thomas*, 5000, 5063-66.

On animals not of very much importance, *Corfield*, 5115. Results should not decide a matter, 5116, 5120; such as dosing children with drugs, 5117-18. Known action of the drugs on the human economy is the point of importance, 5121; and avoidance in the absence of such knowledge advocated, 5122.

On animals valuable on certain defined lines, monkeys being preferred to cats or dogs, *Grinbaum*, 6482; and with positive results as to preservatives, 6488-90. But weight for weight and age for age, animals stand unnatural food better than the human, 6482-83. Pig said to approximate to man in structure, 6484-87.

*In vitro* not deemed important, *Still*, 6818-20. With artificial gastric juice are reliable, but harder on the antiseptic than those on the living subject, *Sturling*, 6988-91.

## 31a. ANIMALS, ADULT :

Animals used by Rideal and Foulerton too old, *Boyce*, 2726.

Feeding of animals with formaldehysed food has no effect on the nutrition of cats, guinea-pigs, or rabbits, *Rideal*, 3687.

One animal fed first on formaldehysed and later on boracised milk gained considerably in weight, *Rideal*, 3689-90.

Committee should undertake, *Stevenson*, 4855-56.

## 31b. ANIMALS, YOUNG :

Preferable to adult animals and *in vitro*, *Annett*, 2673-74.

## 31. EXPERIMENTS—continued.

## 31b. ANIMALS, YOUNG—continued.

Certain rodents susceptible to diseases affecting the human, to which cats and dogs are not susceptible, *Boyce*, 2718.

Committee should undertake experiments as to effect of preservatives on young animals, such as monkeys, but rate of mortality among the latter a point of objection to their use, *Stevenson*, 4811-19. Such experiments are needed and Committee should undertake them, 4846-47, 4855-56.

## 31c. BORACIC ACID :

On digestion, in foods, *Cripps*, 1936-67.

Less powerful as a germicide and antiseptic than formalin, *Blaxall*, 6061, 6094, and also as a preservative, 6067-69. Boracic acid up to  $\frac{1}{3}$  will not sterilise milk, 6062; fermentation ceases, but organisms grow freely, 6064, 6129. Milk will only take up about  $\frac{1}{35}$ , 6063. In  $\frac{1}{100}$  milk sours in 24 hours at 80° F., 6064-65. In  $\frac{1}{500}$  no effect in keeping milk sweet during summer weather, 6096-98; and would not prevent formation of lactic acid, 6099-101; but  $\frac{1}{500}$ , an undesirable amount, would keep milk sweet for 24 hours at 70° F., 6108. About  $\frac{1}{100}$  or five grammes per pint will produce inhibitive action in milk, 6127-29. A proportion altogether in excess of the Pharmacopoeial dose requisite to keep milk sweet, 6130. Inhibitive action of boracic acid apart from milk not experimented on, 6131-32.

Liebriech's pamphlet on the action of borax thought of as biased, *Halliburton*, 7558-64. Boracic acid least harmful of preservatives, 7578-79. Experiments of Foster and Chittenden known; latter shows boracic acid as innocuous in certain quantities in the case of dogs, 7591-94.

## 31d. CATS :

Cats are carnivorous, *Boyce*, 2715.

Commonly made, *Boyce*, 2717.

Cats sometimes affected by tuberculosis, *Boyce*, 2719.

Of little value as compared with the human economy, *Tubb-Thomas*, 5067-69.

## 31e. DOGS :

Almost worthless, *Boyce*, 2713.

Commonly made, *Boyce*, 2717.

Dogs sometimes affected by tuberculosis, *Boyce*, 2719.

Of little value as compared with the human economy, *Tubb-Thomas*, 4993-96.

Economy of dog more resistant than that of man, *Halliburton*, 7565-66; metabolic processes of dog and puppy much the same, but diet varies, 7567-68.

## 31f. DOGS : Boracic Acid :

Chittenden's experiments made on full grown dogs, and hence differ in results from Annett's on kittens, *Annett*, 2664.

On dogs do not show much against boracic acid or borax as used in foods, *Starling*, 6944.

Chittenden shows boracic acid to be innocuous in certain quantities in the case of dogs, *Halliburton*, 7591-94.

## 31g. FEEDING :

If systematic, would be important, *Walford*, 1899-1900.

Meagre on Continent, *Boyce*, 2729-30, 2739-41 (footnote).

Proceeding in Berlin, as to boracic acid, *Boyce*, 2730.

## 31h. FORMALDEHYDE :

Strength of  $\frac{1}{1000}$  used, *Cassal*, 3834.

Resulting demonstrations of small effect of use of formic aldehyde as evidenced by Dr. Rideal's experiments, not known, *Foulerton*, 4077-81.

Fish died in a few hours when subjected to  $\frac{1}{1000}$  formic aldehyde;  $\frac{1}{1000}$  had no effect on action of frog's heart, *Foulerton*, 4138, 4141, 4163-66.

## 31. EXPERIMENTS—continued.

## 31h. FORMALDEHYDE—continued.

Experimental work done as to preservatives in food, *Blaxall*, 6044; as to sterilisation of milk by formalin, 6045. Age of milks used in experiments not known, but deemed of recent milking, 6066, but element of uncertainty in results, herefrom, 6085. Experiments made on scientific basis, not from a commercial standpoint, 6071-73. Commercial usage of preservatives not known, 6074-76. Experiments made from May up to and during winter, 6115, all milks tested for formalin, but not all for boracic acid or salicylic acid, 6053, 6116-18, and no reason to suspect their presence, 6118-25. Bacilli in experimental milk not differentiated, 6126.

Formalin in  $\frac{1}{500}$  kills all germs in milk, which latter can be kept indefinitely, *Blaxall*, 6046-51. Method of procedure adopted, 6052-54. Thirty-eight experiments made, 6059. Control unpreservatised milks nearly all went sour in 24 hours, in hermetically sealed flasks, 6055. Sour milk preservatised had as many organisms as the control milk; but sweet milk, not so, 6056. Bacteriological fermentation not seasonally different under the conditions of the experiments, 6057-58. Formalin  $\frac{1}{1000}$  will keep milk sweet for a short time, 6078, possibly 24 hours at 60° F., 6079, not at 80° F., 6080-82, the 24 hours being it may be from 36 to 50 hours after milking, 6083-84. In  $\frac{1}{5000}$  formalin no use for keeping milk 24 hours in summer weather, 6086-91, 6095, 6098, and would not prevent formation of lactic acid, 6099-101, but  $\frac{1}{500}$  would keep it for 24 hours at 70° F., 6107. Specific action of formaldehyde on the constituents of milk not known, 6092-93. Formalin of experiment guaranteed as a 40 per cent. solution but not tested, 6112-14. About  $\frac{1}{1000}$  would kill typhoid bacilli, 6142, and  $\frac{1}{500}$  any bacteriological organisms in milk, 6146, and render milk unsaleable, 6151. Formalin hardens sections, 6143-44. Organisms in milk diminish rapidly on addition of formalin, 6147-48. Volatile nature of formalin not known, 6149-50.

Experiments made as to physiological action of formalin, *Starling*, 6938; with formalin in  $\frac{1}{1000}$ , 6960-62. Experiments of Drs. Rideal and Foulerton as to formalin not known, 6957-59.

## 31j. GUINEA PIGS :

Almost worthless, *Boyce*, 2713.

## 31k. KITTENS :

On young kittens important, *Boyce*, 2713.

Digestion resembles the human, *Boyce*, 2714. Food approximates to that of infant, *Annett*, 2668; *Boyce*, 2716.

Difficult to feed successfully: some kittens fed on formaldehysed milk,  $\frac{1}{5000}$ , and boracised milk,  $\frac{1}{2000}$ , and taking 70 c.c. of milk per diem, increased in weight, *Rideal*, 3688-89.

Dr. Annett's experiments on boracised kittens of value, and should be carried on upon a larger scale, *Stevenson*, 4805.

Kittens approximate more nearly to the human than cats and dogs, *Tubb-Thomas* 4996-99.

Demonstrate harm by boracised and formalised milk, *Hope*, 6830.

Experiments of Dr. Annett not known, as to boracised kittens, *Halliburton*, 7569-70.

## 31l. KITTENS : Boracic Acid :

Feeding with 80 and also 40 grains per gallon of milk, led to emaciation and death, *Annett*, 2647; kittens had diarrhoea, 2648; probably voided balance of unassimilated nutriment, 2649. Control kittens used, 2650. Amount of boracic acid taken not known, 2653-55, 2690. Ten boracised kittens took about a quart of milk daily, 2656-59. Kittens hardly susceptible to boracic acid after three months old, 2660, 2662, 2671-72, 2694, 2704. Susceptibility decreases gradu-

## 31. EXPERIMENTS—continued.

## 31l. KITTENS : Boracic Acid—continued.

ally, 2695, 2698-2701. *Vice versa* experiments on kittens not attempted, 2660-61. Relative immunity of infants not known, 2696. Older kittens used by Rideal and Foulerton led to different results, 2663, 2691-93. No experiments on kittens fed normally till three months old; Foulerton obtained no results with kittens so old, 2703, 2705; kittens, like infants, depend on milk diet, 2668.

Boracised milk not so appetising as undoc-tored milk, *Boyce*, 2721-22, 2727-28.

Of little worth, *quâ* human analogy, *Bond*, 3103-4.

## 31m. KITTENS : Formaldehyde :

Growth retarded if used in milk  $\frac{1}{5000}$ ; greater retardation in  $\frac{1}{3500}$ , and still greater in  $\frac{1}{1250}$ , *Annett*, 2640-41.

Formaldehysed milk not so appetising as undoc-tored milk, *Boyce*, 2720.

## 31n. KITTENS : Preservatised Milk :

Continued dosage tends to immunity, and natural immunity comes on about three months of age, *Boyce*, 2731.

## 31o. LABORATORY :

Do not typify human conditions, *Walford*, 1865-66, 1898.

Outside human body, not generally of much account, *Cripps*, 1955.

As to injurious results of preservatives in food must be long-continued to be conclu-sive, as in the case of water-borne lead poisoning, *Mann*, 2611.

## 31p. SALICYLIC ACID :

Experiments made with salicylic acid showed retarding effect on digestion of boiled white of egg, but not on pancreatic digestion, *W. C. Williams*, 5196.

As to digestive action, *Starling*, 6938.

## 32. FACTORIES :

## 32a. BUTTER, IRISH :

Normandy style general, *Dale*, 246; *Shanahan*, 488.

Processes described, *Shanahan*, 350.

Butter of different farms blended, *Shanahan*, 367-68.

System greatly improved, *Shanahan*, 387-88.

Butter milk and water expressed, *Shanahan*, 351.

Supplied once or twice a week, *Shanahan*, 457-59, 488.

Send butter to London, preservatised, *Hudson*, 495-96.

Make secondary quality, with salt and preser-vatives, *Riley*, 820.

Factory and creamery butter not discrimina-ted, *Long*, 4645-47.

Factory butter not touched at creameries, *Lough*, 6642. A source of annoyance to creameries, and often sold as creamery butter, 6643. It is not creamery butter, 6644. It is different from, 6645; and inferior to creamery butter, 6646. Irish and Normandy factory butters of very different class, greatly in favour of the latter, 6647.

## 33. FISH, PRESERVATISED :

When unfit for food, rendered saleable by use of boracic acid, *Handford*, 2278.

Crosse and Blackwell use no preservatives in potted fish, *Blackwell*, 4868-70.

Should not be preservatised, *Dupré*, 5907-12.

Boracising of fish given up, *Hope*, 6915; because flavour was destroyed, 6916. Boracising of oysters not known, 6919. Oysters having 38 grains of boracic acid to the lb. objected to, 6920-21.

Formalin heard of as used for fish, *Hope*, 6917; but not inquired about, 6918.

Fraud goes on as to so-called "smoked" food, *Poore*, 7383-85. "Smoked herrings" painted with pyroligneous acid 7385

## 34. FLAVOUR :

## 34a. BORACIC ACID :

Nearly tasteless, *Williams*, 2139.

Eighty grains per pint would taste milk, *Bannister*, 3637-38, 3640.

To taste a food, must be present in excessive amount, *Stevenson*, 4832.

Has no aroma, *Harris*, 6004-6.

Has no flavour, *Attfield*, 6551.

## 34b. BORAX : Butter :

Unpleasant in excess, *Kellitt*, 43.

Heavy quantity would lead to rejection, *Bennett*, 211-13, 216-17, 228-31.

Heavy quantity needed to produce aroma, *Bennett*, 215, 218.

## 34c. BORAX : Meat :

Would taste meat if amount used were appreciable, *Bennett*, 150.

Injection into meat would impart flavour, *Bennett*, 192.

People would not eat flavoured hams, *Davidson*, 1591.

## 34d. BORAX AND BORACIC ACID : Butter :

Distinct, *Clement*, 1519.

Boracised butter used for cooking (say) fish would tend to saponify the fat, *W. C. Williams*, 5232-42.

Tastes butter, and public taste is getting seasoned to it, *Hegner*, 5605.

Boracic acid in 1 per cent. solution tastes butter, *Sorensen*, 7125-28, 7146-50. Two per cent. would render butter useless for this reason, 7161-63.

## 34e. BUTTER :

Soil, vegetation, or food generally does not affect flavour of butter; but the bacterial life does, *Faber*, 4296-99, and pasteurisation obviates all "feed taste," 4300. Flavour is produced by fermentation, 4304-5, 4308, not by breed of cattle, 4306-7, 4333.

## 34f. BUTTER, Irish :

Flavour of salt preservatised butter milder than such butter without preservative, *Gibson*, 6356.

## 35. FLUORIDES IN FOOD :

Heard of, but not found, *Vasey*, 2044-45.

## 36. FLYBLOW :

## 36a. BACON :

Prevented by borax, *Kellitt*, 11, 12, 23; *Prossor*, 567; *Gregson*, 873, 881-82.

Used to cause loss in summer, *Kellitt*, 41.

Rarely seen now, *Kellitt*, 41.

Only seen where meat is moist, *Kellitt*, 41.

Occurs after cure, *Gregson*, 919-20.

## 37. FOOD :

## 37a. ASSIMILATION :

Remains in the stomach some two or three hours, *Cameron*, 2562.

## 37b. CLASSIFICATION :

Desirable and feasible, *quâ* use of preserva-tives, *Vasey*, 2002-3, 2050, 2059-64.

## 38. FOODS, FRESH :

## 38a. BUTTER :

Vastly different to salt, *Clement*, 1556.

For immediate use not preservatised, *Clement*, 1526.

Is unsalted in the trade, *Clement*, 1560-71, 1573-79, 1581-82; *Hill*, 2507.

May be months old, *Hill*, 2508-14; if pre-servatised, *Clement*, 1572.

Not necessarily fresh made, *Clement*, 1576-80, 1583.

From Dunmagit is fresh, saltless, and quickly consumed, *McCracken*, 2854-55.

Danish so-called in England; in Scotland fresh butter is saltless and unpreservatised. *McCracken*, 2861.

Must now be absolutely so, *McCracken*, 2951.

Danish butter, containing 1 per cent. of salt, does not compete with "fresh" butter, *McCracken*, 2952-53.

38. FOODS, FRESH—*continued*.38a. BUTTER—*continued*.

Slightly salted butter is "fresh" on the market, *Long*, 4642.

Bulk goes to better class; demand for saltless butter may have to do with use of preservatives, *Hehner*, 5596-5600.

Aylesbury Dairy Company's fresh butter sales increasing, *Hattersley*, 5837. Company's sale doubled in five years, 5838. Why, not known, 5839-40.

## 38b. FOOD:

Fresh food most important, *Poore*, 7346-47; and productive of energy, as instanced by animal life, 7350-60; and preservative food different from fresh food, 7348-49. There should be no confusion between fresh and preserved foods; even frozen meat loses its flavour, and a great deal becomes flabby and unappetising, 7361. Salt meat speaks for itself, 7362; whilst preservative and preserved foods do not, 7363. People should be able to get fresh food, 7373; and should use it in due proportion, 7376. It should be produced near centres of population, 7418. Preserved food inevitable, 7374; and demanding its place in dietaries. Best mode of preservation should therefore be adopted, 7375. Fresh and preserved foods should be differentiated, 7391-93. Preservatives may deceive on this point, 7383-85, 7412-13. Nutrition much to do with susceptibility to fatal disease, 7394-97.

## 38c. MEAT:

Imported, not preservative, but mildly cured

on arrival in brine only, *Davidson*, 1632-34.

Dusted with borax, *Handford*, 2280; if kept, *Bannister*, 3626.

Imported in refrigerators, *Bannister*, 3487.

## 38d. MILK:

Is recently from the cow, and unpreservative, *Hill*, 2502-4.

To restrict, as fresh milk, the sale of milk not fresh would be a hardship on distant milk-service vendors, *Cassal*, 3939-40.

Boracised milk held to be "fresh," *De Hailes*, 3970-71.

Almost impossible for London poor to get it at present, *Foulerton*, 4058-59.

New and unadulterated, seldom preservative, in Liverpool, *W. C. Williams*, 5149, 5155.

Milk preservative soon ceases to be fresh milk, *Poore*, 7349. Advantage gained if milk kept from going putrid, 7364; or if germ growth be inhibited; but milk treated for the consumer is not like the milk as drawn from the udder, 7365, 7420. A great thing to give people wholesome milk, 7420. Modern conditions among the poor for keeping milk very bad, 7419.

## 38e. PROVISIONS:

Use now general, *Kellitt*, 56.

## 39. FRUITS, BOTTLED:

Sterilised by Messrs. Keiller, *Boseley*, 1062;

Messrs. Keiller do not colour, *Boseley*, 1148-51.

Made without preservatives, but colour goes off somewhat, *Long*, 4664.

## 40. GERMICIDAL POWER:

## 40a. ANTISEPTICS:

Have some selective action on bacteria, *Cameron*, 2564-72.

Antiseptics not necessarily destructive of all bacteria, *Womack*, 7487-88.

## 40b. BORACIC ACID:

Would lose restraining power if milk diluted, *McFadyean*, 1772.

Does not remove signs of putrefaction, *McFadyean*, 1767.

Feeble, but restraining, *McFadyean*, 1772.

Micro-organisms found to have multiplied in boracised milk, *Mann*, 2613-16.

Would scarcely inhibit growth of bacillus coli communis and enteritidis sporogenes in milk, *Boyce*, 2750.

40 GERMICIDAL POWER—*continued*.40b. BORACIC ACID—*continued*.

On certain bacteria, inhibitory rather than destructive, *Foulerton*, 4195-97.

Not a germicide rather an antiseptic, *Richmond*, 5742-43.

Borax a more efficient antiseptic than boracic acid, *Halliburton*, 7548.

## 40c. FORMALIN:

Would scarcely inhibit growth of bacillus coli communis, or enteritidis sporogenes, milk, *Boyce*, 2750.

On certain bacteria, inhibitory rather than destructive, *Foulerton*, 4195-97.

A marvellous antiseptic, *Halliburton*, 7548.

## 40d. PRESERVATIVES:

Restraint must be attained, if use effective, *McFadyean*, 1782.

No experiments made as to bacterial growth in preservative milk, *Boyce*, 2747-48.

Preservatives' antiseptic power in relation to toxic equivalents not known, *Blaxall*, 6109-10; but important, 6111. Preservatives have a selective action on organisms in milk, 6133-36.

Germicidal power of preservatives different on different bacilli, *Blaxall*, 6140-42.

## 41. GLACIALINE:

Sold in sixpenny boxes, *Cameron*, 2531.

And boracic acid, only boric compounds known in Leeds, *Cameron*, 2537-38.

Implicated in cases of serious illness in Dover, in association with boracic acid in milk, *Robinson*, 3301, 3327, 3345.

Used in Broadstairs milk, *Robinson*, 3309.

Borax and boracic acid commonly admixed in; *Halliburton*, 7544.

## 41a. MEAT:

Used formerly by Newport (Mon.) pork-butchers, 4 ozs. to 40 lbs. of meat, *Jones*, 1395-98.

## 42. HAM:

## 42a. CURE:

Generally with the sides, *Kellitt*, 70.

Boracised at same time, but distinction between cure by, and packing in, borax not drawn, *Williams*, 2229-30, 2232, 2234-35.

Could not be effected by dipping in boracic acid solution, *Williams*, 2233.

By 0.6 per cent. of boracic acid, *Bell*, 2823.

## 42b. PICKLING:

American, some pickled, *Kellitt*, 26.

Nature not known, *Kellitt*, 26.

Preservative pickling not suspected, *Kellitt*, 26-28.

## 42c. SALE:

American, within a week of reaching retailer, *Kellitt*, 60.

## 42d. SMOKED:

At home, as a rule, *Prossor*, 595.

## 43. IDIOSYNCRASY:

## 43a. BORACIC ACID:

May cause toxic symptoms, *Wild*, 1463-66.

Some people may be very susceptible, and may take large amounts in food, *Walford*, 1847-49.

Found not to irritate witness, *Boyce*, 2752.

Witness idiosyncratic to boracised cream, *Blyth*, 3472.

Idiosyncrasy of witness to boracised milk and food, and to boracic acid as a drug, *Tubb-Thomas*, 4930, 5014-15.

## 43b. PRESERVATIVES IN FOOD:

Most children and invalids idiosyncratic, *Tubb-Thomas*, 5016.

Matter of importance *quod* preservatives, *Attfield*, 6569.

Idiosyncrasy probably not of much account *quod* preservatives, *Hutchison*, 6749-50.

## 44. INFANTS AND INVALIDS :

## 44a. FOOD :

Should not be chemically preserved, *Vasey*, 1992.  
Ten years ago practically all such foods preserved, not so now, *Vasey*, 1993-94.

## 44b. MILK, PRESERVATISED :

Exposed to unnecessary danger thereby, *Jones*, 1309, 1362, 1365.  
Not safe, *Wild*, 1429.  
Possible ill effects outweighed by benefits, *Wild*, 1458.  
Children on milk diet would suffer, if useful amount used, *McFadyean*, 1753.  
Child might take an enormous dose of boracic acid, *McFadyean*, 1769.  
Fourteen grains per quart might be harmful, especially to an infant, *Walford*, 1834.  
Milk should not contain preservatives, *Vasey*, 1992, 2099, 2100; *Williams*, 2122-23; *Rideal*, 3694.  
Boracised milk in children's hospital given up on account of observation in one case of infantile diarrhoea, *Handford*, 2267, 2313.  
Would tax infants' digestive powers, *Annett*, 2689.  
Not proper for invalids or children, *Foulerton*, 4147-48, 4152.  
Should not be given to the sick, because of effect on digestibility by boracic acid, and hardening effect of formalin, even in small quantities; nor to children, *Stevenson*, 4803-6.

## 44c. INFANTS AND INVALIDS :

Boracic acid should not be used in milk for infants and invalids, *Corfield*, 5075.  
As a diet for infants and invalids, milk on a different level to other foods *quâ* preservatives, *Corfield*, 5135.  
Milk of paramount importance *quâ* preservatives as being in cases an entire diet; not so butter, *Dupré*, 5906.  
Conceivable that infants may suffer from preserved milk; no evidence of such suffering in witness's possession; and Dr. Bell gives evidence to the contrary, *Attfield*, 6552-54. A question of quantity arises, 6555-56.

## 44d. PRESERVATIVES IN FOOD :

Infants and invalids should not be subjected to indiscriminate use of preservatives in food, *Kaye*, 5509-12. Actual evidence of harm is not great; but there is such, and certainly presumptive evidence as to boracic acid, 5513.  
Harm to infants from preservatives difficult to trace, *Hope*, 6908-9.

## 45. IPECACUANHA WINE :

Salicylic acid found, *Hill*, 2364; offence serious, leading to proceedings in Wolverhampton, *Hill*, 2365-67; no proceedings taken in Birmingham, *Hill*, 2425-35.

## 46. JAMS :

Messrs. Keiller's, except apricot, from pulps made from fresh fruit, *Boseley*, 1009.  
Appearance everything, *Boseley*, 1086.  
Imported pulp cheapens jam, and must be preserved, *Voelcker*, 1707-8.

## 46a. BENZOATE OF SODA :

Used by one London firm, *Boseley*, 968.

## 46b. BENZOIC ACID :

Sometimes used, *Boseley*, 968.

## 46c. SUGAR :

Best beetroot used by Messrs. Keiller, *Boseley*, 1159-60.  
Most effective when boiled with the fruit, *Boseley*, 1161-65.

## 47. KEEPING POWER :

## 47a. BACON :

With borax a month in reasonable weather, *Gregson*, 889-90; much longer if thoroughly cured and very dry, *Sinclair*, 935, 943.

## 47. KEEPING POWER—continued.

## 47b. BUTTER :

Trade demands a month, *Sandes*, 107; *Riley*, 849.  
Nine months unnecessary, *Sandes*, 111, 112.  
Best in dry butter, *Lovell*, 769.  
Trade requires a week, *Lovell*, 796-800, 805.  
Week longest possible (unpreservatised), *Lovell*, 804.  
Weather affects, *Lovell*, 740.  
Depends on preservatives, *Riley*, 850.  
Imperfect make tells against, *Riley*, 851.  
Cannot be determined by examination, *Riley*, 852.  
Texture does not affect, *Riley*, 853-54.  
Of preservatised butters not tested, *Boseley*, 1005-8.  
Will go wrong without preservatives, *McFadyean*, 1762.  
Trade requirements would be met by two or three months, *McFadyean*, 1788-89.  
Preservatives must be used if butter intended to be kept, *McCracken*, 2858.  
Pasture does not affect, *McCracken*, 2949.  
Depends on use of preservatives, *DeHailes*, 4025-26.  
Well made butter without preservatives keeps for six weeks, *Long*, 4642.  
Keeping butter leads to decomposition in three ways, *Richmond*, 5716-18; dry butters tend to keep better than moist, 5719-24, but the action of water can be counteracted by salt, 5725. Trade purposes of Aylesbury Dairy Company served by ability of butter to keep one week, 5728. Action of preservatives on butter chiefly chemical or chemico-biological, 5755-58.  
Preservatives needed because butter required to keep. If used fresh, need for preservatives would be less, *Lough*, 6626. Keeping power of butter greater when both pasteurised and preservatised, 6682. Salt must be used if butter be kept some time, 6685-86.

## 47c. BUTTER : Australasian :

Should be made to keep a month out of cold store, *Trengrouse*, 663-73.  
Keeps sweet three weeks out of cold chambers certainly in winter, *Riley*, 846-48.  
Equally well for 6 weeks with or without preservatives, *Voelcker*, 1682, 1723-29.

## 47d. BUTTER : Borax and boracic acid :

One per cent. kept butter nine months, *Sandes*, 107-10.  
Three-quarters per cent. keeps butter for three or four months, *Dale*, 250, 282, 290-91.  
One-half per cent. keeps butter three or four days, *Lovell*, 725, 783, 793.  
Will only keep butter a month at most, *Lovell*, 803-4.  
On wrappers will not keep butter, *Lovell*, 807-8.

## 47e. BUTTER : Brittany :

Needs rapid, day by day, consumption, if not preservatised, *Trengrouse*, 632-36.

## 47f. BUTTER : Canadian :

Preservatised, has been kept three months, *Hudson*, 549-50.  
Refrigerated, inferior to Colonial preservatised, *Clement*, 1508-10.

## 47g. BUTTER : Danish :

Better than English, *Kellitt*, 45-47.  
Consumed more quickly than Irish butter, *Dale*, 249, 301-2; *Shanahan*, 401-3.  
Deteriorates if kept long, *Dale*, 300.  
Travels far in competition with local produce, *Dale*, 313-15.  
Better than Irish, *Shanahan*, 364-66.  
Inferior to Irish heavily salted butter, *Shanahan*, 399-400.  
Inferior to Colonial, Normandy, or Irish, *Hudson*, 502-4; *Lovell*, 718.  
Difficulty in keeping it, *Trengrouse*, 631, 654.  
Keeps longer than Brittany, *Trengrouse*, 694-96.  
Good as any, *Riley*, 819.  
Keeps with or without salt, *Riley*, 833.

47. KEEPING POWER—*continued*.47g. BUTTER, Danish—*continued*.

Lost, *Clement*, 1516-17.

Butter for quick consumption, *Dunn*, 3035.

Does not keep long, *De Hailes*, 4019-22.

Keeping quality of Danish butter keeps it for a minimum of some three weeks, *Faber*, 4223, 4227, in summer and much longer in winter, 4318-22, for some seven weeks, and then it is sold as fine fresh butter, 4323-26, at top price, 4327-31. Price hangs on many factors, 4332. Results of experiments as to keeping quality promised, 4339 (App. No. 26). The butter not improved by preservatives, 4225, if butter well made, 4226. Nearly exclusively made of pasteurised milk, 4227, by reason of an Act aimed at checking the spread of tuberculosis in cattle, 4228. Keeping quality as good as ever, 4276. Some butter will be three weeks old on reaching retailer, 4278-79, being salted butter; saltless butter consumed more quickly, and only some two per cent. of whole export trade, 4280. One per cent. of salt will keep butter three weeks, 4281. The more water the poorer the keeping power of butter, 4282. Some 14 per cent. of water in Danish butter on shipment, 4283, some of which evaporates in transshipment, 4284. Probably more in Irish butter, 4285-89, though no necessity for it, 4290, and probably little difference in well-made Irish butter, 4291-95. Normandy factory butter drier than Danish, 4301. Its flavour varies, 4302, and the finest goes to Paris, 4303.

## 47h. BUTTER: Irish:

Will keep for a long time, *Dale*, 273, 277; would be affected by prohibition of preservatives, 248.

Poor, demanding a preservative, *Shanahan*, 441-49.

Varies on adjoining farms, *Shanahan*, 365-66. Preservatised butter known to keep well, *Shanahan*, 398.

Heavily salted, better than Danish, *Shanahan*, 399-403.

Never kept beyond a fortnight, *Shanahan*, 460-64.

Some mild-salted, unpreservatised, will keep for three weeks, *Shanahan*, 469-73, 477-78.

Not affected by period of lactation of cow, *Shanahan*, 479-82.

Affected by moisture of butter, *Lovell*, 768-69.

Not aware of failure of Danish instructors to produce Irish butter of Danish keeping quality, *Voelcker*, 1735-36, 1738.

May be affected by uncleanness, *McFadyean*, 1762-63.

Not very good, *McCracken*, 2938-43.

Keeps well, *Dunn*, 3024.

Dry salted butter and warm pickle butter keep equally well, *Dunn*, 3025-26.

Depends on expulsion of buttermilk and water, *Dunn*, 3029.

Mountainous country butter commonly believed to keep best, *Dunn*, 3029.

Not affected by amount of water present, *Dunn*, 3032-33.

Salted butter used to be stored for months, *Dunn*, 3036.

Neither pasture nor manufacture held to render it inferior to Danish, *Long*, 4644.

Keeping power of Irish saltless butter under one week, without preservative, but a fortnight at any rate with preservative, *Gibson*, 6314. Salt preservatised butter keeps for four months, 6315-16, 6376.

Irish butter essentially a keeping butter; not so Danish and Normandy, 6317.

Butter experimented on, kept nine months with preservative added, *Gibson*, 6364. Irish butter keeps much longer than Danish, 6393.

## 47j. BUTTER: Normandy:

Requires rapid consumption, *Trengrouse*, 632. Goes into consumption at once, *Lovell*, 725, 793-95, 801-2.

Better than Danish now, *Lovell*, 726.

47. KEEPING POWER—*continued*.

## 47k. BUTTER: Preservatives:

Keeps a month, *Sandes*, 87.

Boracised better than heavily salted butter, *Sandes*, 107-10.

Butter will keep till needed, *Shanahan*, 390-94.

Regulates price, *Shanahan*, 395-97.

## 47l. DAIRY PRODUCTS: Formalin:

Milk unchanged for months with  $\frac{1}{2000}$ , *Boseley*, 992, 995-97, 1002.

In  $\frac{1}{5000}$  not always effective for 48 hours, nor for 24 hours in  $\frac{1}{2000}$ , but  $\frac{1}{12500}$  keeps milk for 48 hours, *Annett*, 2642-44.

Milk can be kept sweet by  $\frac{1}{5000}$ , *Foulerton*, 4048-49, 4080, 4088-91.

Mr. Thomson held that  $\frac{1}{5000}$  formic aldehyde kept milk sweet for a week at room temperature, *Foulerton*, 4086-87.

## 47m. MARGARINE:

Not known to be inferior to butter, *McCracken*, 2858.

Bettered by preservatives, enabling margarine to keep as long as salt butter, *McCracken*, 2882, 2884, 2992-93.

Contained milk makes it "go off," *McCracken* 2885-90.

## 47n. MILK:

Ten to 12 hours old when distributed, *Boseley*, 1022, 1024-25.

Should keep 24 to 36 hours, thus requiring a preservative, *De Hailes*, 3914-15.

Affected by surroundings, *Voelcker*, 1739.

Affected by health of cow, *Voelcker*, 1740-42.

In large quantities, not known, *Annett*, 2645-46.

Milk difficult of manipulation without boracic acid, even when pasteurised, *Bell*, 2839-44.

Cooling will aid, but not long in hot weather, *McCracken*, 2872.

Skim milk changes just as quickly as new milk, *McCracken*, 2906.

Refrigeration assists, *McCracken*, 2923.

Depends on conditions of storage, *Brierley*, 3176.

Preservatised milk goes bad rather than sour, *Brierley*, 3178, 3254-55.

Should keep 60 hours; but a time limit of 24 hours preferable, *Brierley*, 3256-58.

Can be kept for 24 hours even in warm weather by formaldehyde,  $\frac{1}{5000}$ , or a mixture of borax and boracic acid,  $\frac{1}{2000}$ , or if added at time of milking,  $\frac{1}{15000}$  of formaldehyde would suffice, *Rideal*, 3681, 3697.

Preservatised milk can be kept sweet overnight, *Rideal*, 3762-71.

Will not keep for 24 hours in extreme heat even if cooled, *Foulerton*, 4115-19, 4134-35.

Keeping quality of milk affected by temperature, *Carrington Smith*, 4427, but greatly dependent on cooling, straining, and cleanliness, 4504-15.

Depends on many phases of cleanliness, *Long*, 4588.

Properly treated milk will keep 48 hours under all circumstances, *Tubb-Thomas*, 5041-44.

Keeping quality of preservatised milk matter of experiment, *Richmond*, 5714-15 (App. No. 31). Trade purposes of Aylesbury Dairy Company served by ability of milk to keep 18 hours, 5729, and should be so for all trade purposes, 5730-31. No need for preservatives to secure this, 5732. At 70° Fahr. milk keeps sweet for 34 hours, for 22 hours at 80° Fahr., for 15 hours at 90° Fahr. bottled, in a chamber, 5732-33. Highest temperature of milk on first reaching Aylesbury Dairy Company's premises, 77° Fahr.; highest on coming back from a round, 83° Fahr., 5733. Some few complaints of sour milk, 5734-35.

Milk rarely required to keep more than six hours after delivery to houses, *Hattersley*, 5879, or customer would scald it, 5880. Treatment in house important *quâ* keeping power of milk, 5881, 5899.

(See also under Experiments, Formaldehyde.)

47. KEEPING POWER—*continued*.47n. MILK—*continued*.

Storage of unpreservatised milk in the houses of the poor may lead to its going bad before consumption, *Hutchison*, 6761, 6763-66. Exceedingly difficult to get poorer class to properly house milk, 6762.

Milk should contain no preservatives if it can be guaranteed against going bad in consumers' hands without them. Some delivered to Great Ormond Street Hospital goes bad in summer by the time it reaches the children, *Still*, 6789, 6813.

Milk kept sweet for some time by a limited application of cold, *Hope*, 6828.

## 47o. MILK : Boracised :

As ordinarily used, for a limited period only, *Mann*, 2605, 2612.

For 48 hours with 35 grains per gallon, *Annett*, 2647.

Milk can be kept sweet by  $\frac{1}{2000}$  boracic acid, *Foulerton*, 4048-49, 4080.

Mr. Thomson held that  $\frac{1}{2000}$  boracic acid kept milk sweet for a week at room temperature, *Foulerton*, 4086-87.

Milk that kept good with borax added, went bad with a similar quantity of boracic acid, *Halliburton*, 7546-47.

## 47p. MILK : Preservatised :

Dr. Rideal's experiments show not the slightest effect accruing from the use of preservatives in milk in 24 hours, *Foulerton*, 4185-86.

## 48. LARD :

Requires no preservative, if well made keeps a long time, *Bennett*, 206.

## 49. MANUFACTURE :

## 49a. BORAX :

Factory workers enjoy phenomenal health, *De Hailes*, 4036-41.

## 49b. BUTTER : Australasian :

Passes from creamery to factory, *Trengrouse*, 662.

Plenty quite as fresh as Danish, *Trengrouse*, 689.

Still room for improvement in New Zealand butter, *Cameron*, 6303, and measures are taken accordingly, 6304. Butter made at dairy factories and graded by Government inspectors, 6159-60. "Factory" butter as known at home is "milled" butter of second grade in New Zealand, 6161-62. Best butter exported with salt and in many cases Preservitas, 6163-64, principally boracic acid, 6165. A little has been sent absolutely fresh, but bulk with salt, 6166, and a good deal is preservatised, 6167. Milk sent to dairy factories distance of some four miles twice a day, 6185.

Salt added to New Zealand butter to suit taste of consumer, *Cameron*, 6170.

Cooling of milk compulsory in New Zealand, but not enforced according to Mr. Sorensen, *Cameron*, 6290-93.

## 49c. BUTTER : Danish :

Improved methods have led to large export to England, *Dale*, 261-62.

All-year-round trade, *Shanahan*, 415; *Davidson*, 1624-26.

On scientific basis and in bulk, hence successful competition with Ireland, *Lovell*, 750-51.

Cows housed eight months a year, and food plentiful, *Davidson*, 1630.

Tub butter, *Bannister*, 3513-14.

Tuberculosis has nothing to do with dairying system, *Long*, 4670-71.

Inspection made of farms, *Long*, 4665-67.

Cattle housed in Denmark eight or nine months a year, *Lough*, 6654-56, in Ireland from four to six months, 6657.

## 49d. BUTTER : Irish :

Danish methods adopted under instructors, *Sandes*, 115-16.

49. MANUFACTURE—*continued*.49d. BUTTER : Irish—*continued*.

Danish methods would handicap producer, especially in hot weather, *Dale*, 298-99; *Lovell*, 766.

Improved by factory and creamery systems and boracic acid, *Shanahan*, 387-89.

Little made in winter, *Shanahan*, 416-19.

Ireland has nothing to learn from the Danes, *Shanahan*, 487.

Old methods still in use, *Lovell*, 747.

Small quantities made, *Lovell*, 750.

Education of Irish butter makers at fault;

Danes well educated, *Gibson*, 6357-60.

Improved education needed, 6397.

## 50. MARGARINE :

Salt added. Absolutely fresh, not known to be consumed, *McCracken*, 2883.

Not dealt in by Aylesbury Dairy Co., *Hattersley*, 5806.

Not exported from New Zealand, *Cameron*, 6226, nor made there, 6227.

Made in Ireland, *Gibson*, 6371-72.

## 50a. SOLD AS BUTTER :

Often, *Hill*, 2351.

Boracised samples, mostly, *W. C. Williams*, 5173-74.

## 51. MEAT EXTRACTS :

Generally free from preservatives, outside salt, *Fisher*, 4717.

## 52. MEATS, TINNED AND POTTED :

Slightly salted, *Trengrouse*, 642.

Crosse and Blackwell use no preservatives, *Blackwell*, 4868-70.

Generally free from preservatives, outside salt, *Fisher*, 4717.

## 53. MEDICINAL USE :

## 53a. BORACIC ACID :

Prescribed moderately, *Handford*, 2289.

Intermittent dosage recommended because of discomfort following maintained use, *Handford*, 2290-91.

Given in epilepsy; appetite failed, *Handford*, 2295.

Given to infants for thrush, *Cameron*, 2534, up to 20 grains a day without seeming harm, *Blyth*, 3464-66.

Medical men and patients handicapped by unconsciously obtained immunity, *Boyce*, 2737-38.

Studied, *Bell*, 2783-84.

Putridity of urine treated, *Bond*, 3085-86.

Good for thrush, *Brierley*, 3245.

Injury held to have followed, *Robinson*, 3304.

Fallen into disuse; got elsewhere now than in prescriptions, *Corfield*, 5091-92. Some medical men still use it and believe in it, as a drug, *Corfield*, 5138-44.

Harmfulness vouched for on much evidence, *Starling*, 6944.

Internal application of boracic acid not known, *Starling*, 6978.

For treatment of infantile diarrhoea would be bad, *Anderson*, 7213-15.

Boracic acid used medicinally in large quantities has, according to Dr. Church, caused digestive disturbance; not so in small quantity, *Womack*, 7492. Harmful doses were of 15 grains, 7494-96, every four or six hours, 7497. Not aware of 80 grains in a pint of milk, 7498, which would modify Dr. Church's opinion, 7499.

## 53b. SALICYLIC ACID :

For indigestion, not known, *Bond*, 3143.

## 54. MILK :

## 54a. ADULTERATION :

Preservatised samples most frequently adulterated, *Hill*, 2397-98, and poor most likely to get such milk, *Kaye*, 5458, 5490.

Watered milk does not stand special y in need of preservatives, *Hill*, 2399, 2400.

More in poor districts, *Cassal*, 3809-12.

## 54. MILK—continued.

## 54a. ADULTERATION—continued.

Boracised milk held by witness to be "adulterated," not so held by Local Government Board, *Cassal*, 3816, 3865.

## 54b. BACTERIAL ACTION:

Bacterial growth rapid, *Boyce*, 2749.

*Bacillus coli* and enteritidis sporogenes present numerously in sweet milk, *Boyce*, 2750.

Germs of disease killed by pasteurisation, *Bell*, 2842-43.

Bacteria should be kept from milk rather than inhibited when there, *Tubb-Thomas*, 5026.

## 54c. CONDENSED:

"Preserved" milk now held to mean condensed milk, *Foulerton*, 4151.

Injurious for children, *Foulerton*, 4152.

Use of tinned milk increasing, *Kaye*, 5528-30, and used all the year round, 5533-34, but general absence of preservatives therefrom not known, though not held improbable, 5531-32.

## 54d. CONSUMPTION:

Would not be recommended by medical men in large quantities unless guaranteed as free from boracic acid, with mischievous result from such restricted milk diet, *Handford*, 2320-21.

Should be consumed within 48 hours of milking, *Tubb-Thomas*, 4949.

In Midland and Southern counties some 85 per cent. of milk consumed by children and invalids, *Tubb-Thomas*, 5021-23.

Suckling declining in West Riding, *Kaye*, 5527.

## 54e. DELIVERY:

Only one delivery of milk daily at Copenhagen, *Sorensen*, 7034, with advantages affecting consumer, 7035. Cleanliness and prompt cooling of milk enable one delivery to suffice, 7036. One delivery daily would compensate for cost of refrigeration, 7044, and cheapen milk, 7045, with tendency to concentration of vending, 7046, but not of dairying, 7047. Equality of milk standard would also result, 7051-52. One delivery daily suffices for Manchester; hence also probably would for London, 7053. It is now welcomed in Manchester, 7059. Ice is requisite, 7132, but not for delivery twice daily, 7133-35.

## 54f. HOSPITALS:

Hospitals get milk from good companies, *Hutchison*, 6774, and some have analyses made from time to time, 6775. Details of milk contracts not known to hospital medical staff, 6776-79. There can be no objection to contracts, 6780, and reasonable to exclude preservatives in the contracts, 6781.

Desirable that hospital milk should be examined for preservatives, *Still*, 6811. It could be done by arrangement outside, 6812. No preservative found in milk specimens examined from Great Ormond Street Hospital, 6814.

Milk at Liverpool Hospital very frequently analysed, *Hope*, 6884, for preservatives, including nature and amount, 6885-87, 6889-90. Milk should contain no preservatives, 6888, 6891, especially in fever hospitals, as digestive processes are thereby interfered with, 6892.

Milk of Nottingham General Hospital tested for preservatives, *Anderson*, 7193-96.

Milk supply to all hospitals should be examined for preservatives, *Brunton*, 7465.

## 54g. PURE:

More important than unstinted supply, *Walford*, 1912-13.

Should be pure and satisfactory, or its sale relinquished, *Cassal*, 3806.

## 4h. SEPARATED:

Separators introduced in some parts of Devonshire, *Long*, 4594.

## 54. MILK—continued.

## 54h. SEPARATED—continued.

Separated milk dealt in by the Manchester Pure Milk Supply Co., *Sorensen*, 7080-81, demand being some six per cent. of whole milk demand, 7082. Desirable to stop the fraud of selling separated milk as whole milk or admixed with whole milk, 7084-7113. Customers of Manchester Pure Milk Supply Co. dealt with directly, 8157.

## 54j. STALE:

May be sold by reason of contained boracic acid, to prejudice of customer, *Stevenson*, 4826-28.

Sold by aid of preservatives, *Kaye*, 5498-5501.

## 54k. STORAGE:

Often kept in filthy circumstances in poor-district houses, and on vendors' premises, *Foulerton*, 4120-22, 4128, 4170-73.

## 54l. SUPPLY:

Newport (Mon.), local, *Jones*, 1399.

Better to populous places than formerly, *Walford*, 1911.

To Cardiff from home counties, some 8 hours old on reaching consumer, *Walford*, 1919-20.

To rich and poor not on same footing as to guarantee of freedom from preservatives, *Handford*, 2310.

Stringent clause as to preservatives in Leeds Fever Hospital milk contract; no boracic acid found in it; precautions at children's hospital not known, *Cameron*, 2540-44.

To Dunragit creameries some 10,000 to 15,000 gallons daily, *McCracken*, 2875.

Of skim-milk to cities as separated milk in winter, *McCracken*, 2909.

Sent out daily from Dunragit creameries; some may be 24 to 28 hours old on despatch, *McCracken*, 2933-36.

Institutions should be watched, and milk analysed for preservatives, and notes taken as to health of children supplied with the milk, *Brierley*, 3252.

Delivery more frequent prior to use of preservatives, *Brierley*, 3262-63.

No greater difficulty than formerly in getting milk in enlarged Southampton, *Brierley*, 3265-67.

Milk made into butter prior to use of preservatives, now comes to town as milk, *Brierley*, 3278.

Small vendors tend to be crushed out by organised trade, *De Hailes*, 3946-48.

Interests of small vendor not superior to those of the general public, who would not suffer if he disappeared, if milk supply could be otherwise kept up, *Foulerton*, 4062-64.

Large trade in hands of small vendors, *Foulerton*, 4129-30.

Calving is regulated on a fixed basis for Manchester Pure Milk Supply Co., *Sorensen*, 7072-75.

## 55. MOISTURE:

## 55a. BUTTER:

In delicate butters calls for preservatives, *Trengrouse*, 652.

Determines price and keeping quality, *Trengrouse*, 700-1.

## 55b. BUTTER: Danish:

Drier than Irish, *Clement*, 1512.

## 56. NECESSITY FOR PRESERVATIVES:

## 56a. BORAX AND BORACIC ACID: Butter:

Used only on this account, *Lovell*, 749.

To Irish butter trade, *Lovell*, 737, 747; to all butter, especially Australian, *Clement*, 1503-5.

## 56b. PRESERVATIVES:

Not necessary in food generally, and misleading to the public, *Hehner*, 5593, 5634-35.

## 56c. PRESERVATIVES: Bacon:

Essential to mill hands, *Davidson*, 1588.

## 56d. PRESERVATIVES: Butter:

Advised as indispensable, *Kellitt*, 122. To Irish trade, *Shanahan*, 363, 441.

56. NECESSITY FOR PRESERVATIVES—*contd.*56d. PRESERVATIVES—*continued.*

To cold stored butter, *Hudson*, 555.  
 Unnecessary, *Jones*, 1361.  
 Not in butter properly made under proper conditions, *Voelcker*, 1734; *Brierley*, 3189-90.  
 Trade to-day demands a preservative, as regards factory and creamery butter, *Bannister*, 3502-3, 3532, 3536-37.  
 Not for butter quickly reaching consumer, *Hehner*, 5594-95.  
 Butter preservatised by Aylesbury Dairy Company years ago, *Richmond*, 5673; but not now, 5674, 5679. Butter was either washed with a solution or had the acid worked in, 5675. By washing, some of the acid was retained in the butter, 5676; boracic acid itself being used, 5677; and  $\frac{1}{2}$  per cent. added, 5678. Done away with because objected to by the public, 5680-81; and as matter of policy, 5682. No consequential trouble, 5683. Butters imported from France are preservatised, 5684. Percentages of boric anhydride contained handed in, 5685-86. Still sell such butters, 5687. Boric compounds not absolutely necessary in such butters, but trouble may be caused by non-use, 5688. Salt equally efficacious, 5689. Danish butters found free from preservatives, 5691.

## 56e. PRESERVATIVES: Food:

At certain seasons, *Vasey*, 2003.  
 Chemicals unnecessary in food, and objectionable, *Cassal*, 3816.  
 All unnecessary, *Tubb-Thomas*, 4977.

## 56f. PRESERVATIVES: Milk:

Unnecessary for trade purposes, *Jones*, 1309.  
 Ideal milk should not contain them, *Wild*, 1493.  
 Not necessary, undesirable, and as a rule physiologically indefensible, *McFadyean*, 1752.  
 Not requisite, *Williams*, 2170, 2177-79, 2257-58; *Brierley*, 3256; *Long*, 4570-74.  
 Only in winter, *McCracken*, 2878-79.  
 Large town trade demands them as now organised, *Blyth*, 3447-48, 3476-81.  
 Trade requirement counter-balanced by such amounts as 80 grains of boracic acid per pint, *Bannister*, 3641.  
 Great difficulty in large town trade in summer, apart from a preservative, *Bannister*, 3642-44.  
 If only 9 per cent. of Birmingham milk preservatised, no great necessity therefor, *Bannister*, 3645-47.  
 No necessity for milk kept 39 hours at 55 $\frac{1}{2}$ ° Fahr., nor for milk kept 23 hours at 64° Fahr.; and preservative shows little preservative effect on milk, even at the temperature of a summer's day; but just sufficient retardation of acidity of milk to justify the use of preservative, *Rideal*, 3701-61.  
 None for London, *Cassal*, 3803-4.  
 Necessary, and present trade demands them, *De Hailes*, 3928-29, 4003, 4016-19.  
 Required to a certain extent, *Foulerton*, 4047.  
 Large vendors can do without them, *Foulerton*, 4060.  
 Distance an important factor, *Foulerton*, 4061, 4128.  
 Would cease if milk properly stored, *Foulerton*, 4126-27, 4171-72.  
 Birmingham evidence as to 91 per cent. of her milk supply unpreservatised, an element against necessity for preservatives, *Foulerton*, 4131-33.  
 None used by witness in sending milk to London from Mid-Staffordshire, *Carrington Smith*, 4414-15. No complaint of milk lost save as to Sunday milk sometimes, 4416-18, 4515. All, save Sunday milk, in consignees hands in 12 hours, 4419-24. During four winter months milk sent out only once a day, 4425-27. His milk goes to Birmingham now for reasons of price, 4550-52. Milk from Aylesbury Valley sent to London without preservative, 4428-30; but milk cooled,

56. NECESSITY FOR PRESERVATIVES—*contd.*56f. PRESERVATIVES: Milk—*continued.*

4431. Also from Faringdon, Berkshire, in large amount, 4440-41, 4539; and from a point equi-distant with Staffordshire, from 1,500 cows, 4443-46. Cooling and straining of milk render preservatives unnecessary, 4515; in any part of England, 4549.  
 Not necessary in rural districts, and none used as a rule; not necessary in Oxfordshire, *Fisher*, 4717, 4749-51.  
 Not necessary if milk properly cooled, and due regard paid to cleanliness, *Stevenson*, 4801.  
 Large vendors use precautions, which render preservatives unnecessary, *Stevenson*, 4802.  
 Not necessary, even in large towns, *Tubb-Thomas*, 4934-35.  
 Not necessary for Liverpool, *W. C. Williams*, 5289, 5305.  
 Vendors declare them to be necessary, *Kaye*, 5447.  
 Unnecessary, *Kaye*, 5448-50, 5519.  
 No necessity; milk of a large London dairy company free from all preservatives, *Hehner*, 5580-81, 5607.  
 Milk supplied to Aylesbury Dairy Company from distances up to 200 miles, *Hattersley*, 5768-70, 5846; even in summer, 5847; and free from preservatives, 5771-72; as being unnecessary, 5773-76; and from a protectionist policy many years ago perhaps, 5776. Stipulations as to non-use of preservatives with contracting farmers, 5776, 5882-83. Only 78 letters of complaints as to sour milk out of upwards of five million deliveries, 5776-77, 5875; and these chiefly owing to improper treatment of milk by customer, 5832.  
 Preservatives seldom found in Liverpool milk samples, *Hope*, 6828. No necessity for chemical preservatives in milk, 6829, 6837, 6839; even in large towns, 6896. Vendors say public want them, 6838. This is not so, 6839, 6864. Liverpool milk supply comes from a radius of some 50 miles, 6831-33.  
 Milk of Copenhagen Milk Supply Company not preservatised, *Sorensen*, 7022. No preservatives used in milk supplies of towns in Denmark. They are strictly prohibited by law, 7023. They may be used in small villages, 7024; where the law is not so strictly enforced, 7024-27. Dr. Stein known by witness years ago, 7028. He is official analyst to Danish Government, 7029; and his functions extend all over the kingdom, 7030-31. Quite possible to supply large towns with unpreservatised milk, 7032, 7043. Manchester Pure Milk Supply Company use no preservatives, 7033. They get milk from nine farms, 7048-49. Have existed for one year, 7050. Trade increasing, 7130-31. Customers of mixed, but chiefly of middle class, 7151-53. Sanitary conditions of lower classes in English towns perhaps not so favourable to keeping milk as in Copenhagen, 7154-56.  
 Experiments made demonstrate preservatives to be unnecessary in refrigerated milk, *Schidrowitz*, 7223, 7230-31. Experiments described, 7224-29.  
 Milk can be supplied to large towns unpreservatised, *Brunton*, 7428, and should be, 7429.

## 57. NITRATE OF POTASH:

Need not be condemned; rarely met with, *Hehner*, 5636.  
 Should be prohibited as a preservative, *Halliburton*, 7576.

## 58. ORDERS AS TO DAIRIES, COWSHEDS, &amp;c.:

Need enforcement, *Handford*, 2323-24; *Corfield*, 5114.  
 Indifferently enforced, *Kaye*, 5452. Preservatives abet evasion of regulations, 5453-54. Insanitary conditions affect milk, 5479-80.

## 59. OSMIC ACID:

Vapour an irritant, *Boyce* 2756.

## 60. PASTEURISATION:

- Destroys fine flavour of butter, *Lovell*, 727.  
 Destroys keeping qualities of frozen butter, *Lovell*, 727.  
 Given up by Colonies and Argentine, *Lovell*, 728.  
 Fad of the Danes, *Lovell*, 730-31.  
 Expensive, *Lovell*, 730-31.  
 Destroys flavour of cream, *Lovell*, 732-33.  
 Not practised, *Boseley*, 1026-27.  
 Practicable in Manchester, *Wild*, 1437-39.  
 Does not obviate need for boracic acid in milk, *Bell*, 2839-42.  
 Experimentally only at Dunragit creameries; flavours milk objectionably, *McCracken*, 2895-2901.  
 Milk raised to 160° to 170° F., *McCracken*, 2902.  
 Cost not known, *McCracken*, 2903-5.  
 All skim-milk sent from Dunragit creameries, pasteurised, *McCracken*, 2903-5.  
 Not used for preservatised milk, *Brierley*, 3181.  
 Possibly a question of organisation; would doubtless increase price, *Blyth*, 3449-51.  
 If in force in Copenhagen, that a small place compared with London, *Blyth*, 3452-53.  
 Pasteurisation and sterilisation change the character of milk, *De Hailes*, 3964-66, 3972-75, and the change may have grave effects on children and invalids, 3976. Continental general use of cooked milk not known, 3982-84.  
 Pasteurisation of all milk effected by one large dealer, *Long*, 4585-88.  
 Pasteurisation used by some Wiltshire and other dairies, *Tubb-Thomas*, 4980, 4983-84, 4986.  
 Trade springing up, 4982. Milk is bottled, 4985, at same price at Leicester, 4987. Exact temperature not known, 4988.  
 Pasteurised milk has little demand, *Hattersley*, 5783-84; milk heated to 160° F., 5785.  
 Pasteurisation more needed in winter in North than in South Ireland, because of the winter stall feeding of cattle, *Lough*, 6627. Denmark needs pasteurisation for same reason, 6627-28, and to erase feed taint, but butter from field-drawn milk needs no pasteurising, 6629-30.  
 Pasteurisation held to be most valuable, 6631-32.  
 Temperature in pasteurising some 175° to 185° F., 6633. Improvement of milk of house-fed cattle by ferments or cultures not known, 6634-36.  
 Practical difficulties in dealing with large quantities of milk are being overcome, 6690.  
 Milk ideally should be sterilised or pasteurised and unpreservatised, *Hutchison*, 6723, 6760.  
 Sterilised milk has advantages for children, 6724-25. Pasteurisation would be of great good as a germicide, 6726.  
 Sterilisation or pasteurisation and even boiling of milk held to be harmful to children, *Still*, 6791, 6799, especially the former, 6800. Infantile scurvy or mal-nutrition follows prolonged heating of milk to a high temperature, 6792-93.  
 Reason not known, fact remains, 6794, and is well recognised, 6795. The scurvy can be produced by almost any patent food, 6796. The disease increasing, 6797, and is due to such milk and foods, 6798. Freezing of milk might have like effect, 6801, moderate cooling would not, 6802.  
 Pasteurising of milk in Denmark and Copenhagen not universal, *Sorensen*, 7171-74. Manchester Company opposed to the practice, 7175, 7183, as unnatural and injurious, 7176, on medical advice, 7177, as rendering milk indigestible, 7178. It caramelises the milk sugar and coagulates the albumen, 7179, and flavours the milk, 7180-82.  
 Sterilised milk cannot be regarded as the same thing as fresh milk, *Poore*, 7366. What happens to pasteurised milk kept under modern low-class filthy town conditions is matter of serious conjecture, 7419.  
 Pasteurisation of milk likely to alter and render less digestible the proteids in milk, *Halliburton*, 7601-14, but any specific toxic action brought about by boiling of milk must be very slight, and if existing should have been discovered long ago, 7614-21. No poisoning effect to be feared from re-arrangement of inorganic phosphates in milk, 7622-23.

## 60. PASTEURISATION—continued.

## 60a. BUTTER: Australasian:

Pasteurisation in New Zealand used to slight extent, *Cameron*, 6179, with rather unfavourable result, 6198, 6200, by removing the finer taints, 6199, necessitating a ferment, 6200. Quality of pasteurised butter not quite so good as ordinary butter, 6201, 6294-6300, and quality goes off after defrosting, 6202. With perfect milk pasteurisation not needed, 6301-2. Pasteurisation brings up the average of butter, 6305-7.

## 60b. BUTTER: Canadian:

Practised, *Riley*, 820.

## 60c. BUTTER: Danish:

Largely effected, *Lovell*, 727; *Dunn*, 3017.  
 Accounts for good keeping quality, *Riley*, 819.  
 To be commended, *Riley*, 823, 840.  
 Improves butter, *Riley*, 824-26, 841.  
 Employed for some years, *Riley*, 842.  
 Has lessened keeping quality, *Clement*, 1517; *Davidson*, 1596, 1614.  
 Pasteurised, and hence acquires a distinct taste, *De Hailes*, 4023.  
 Sterilisation of milk by two large firms in Copenhagen, *Faber*, 4216, 4258, by pasteurisation; and cream also treated thus, 4217, in 97 per cent. of dairies, 4231, even before requirement that cream be pasteurised, 4309, and milk heated to 185° Fahr., 4218.  
 Pasteurisation does not interfere with flavour of butter, 4228, but colour test can distinguish pasteurised butter, 4229; not so the palate, 4230. It helps fermentation, 4231. Does not flavour milk unless the milk be heated to over 85° C., and need not flavour it, 4248-49; a matter of rapid cooling, 4250, even with 90° C., 4251-53. Raw milk avoided in Denmark; many people boil any unpasteurised milk purchased, 4254-55. Vending of pasteurised milk not the rule, 4256-57. One town demands that milk be pasteurised or drawn from cows which have stood tuberculin test, 4258. All towns have power so to rule, 4260-62. Necessity for pasteurising milk only related to prevention of cattle disease by tuberculosis, 4227-28, 4259. Pasteurised butter adjudged the best, 4309-11. Pasteurisation medically recommended, 4334-36. Milk very often boiled on Continent, 4337-38. Perhaps 25 per cent. of Copenhagen milk supply pasteurised, 4340-43, and milk brought from distances of 120 miles, 4345-46. Infantile mortality of town not known, 4344. Milk cooled prior to train journey, 4347-48. Cost relatively to large trade small, 4349. Small farms cool with water, and factories or dairies with ice, 4350-52. Committee would be welcome to see Copenhagen method of treatment; that of Pasteur Milk Supply commended, 4353. Reference to bouquet of cream as produced by fermentative agents promised, 4357-59.  
 Danish butter is from milk practically sterilised, and then re-inoculated by flavour germs, tending to keep it sweet, *Long*, 4667.

## 60d. BUTTER: Irish:

Cork creamery uses, *Dunn*, 3017.  
 Factory butter could not be pasteurised, *Dunn*, 3017.

(See also Sterilisation.)

## 61. PEAS:

## 61a. CONSUMPTION:

May be two or three years old, *Copeman*, 1234.  
 No one would eat more than  $\frac{1}{2}$  lb. of preserved peas, *Copeman*, 1275-76.  
 Dry marrowfat peas largely used for soup, &c., *Copeman*, 1277-79.  
 In 5 ozs. of peas more than one grain of copper, *Copeman*, 1301.

61. PEAS—*continued*.

## 61b. DETERIORATION :

Takes place after two or three years, *Copeman*, 1235.  
Thick and cloudy in 7 or 8 years, *Copeman*, 1293-94.

## 61c. DIGESTION :

Peas would naturally remain in alimentary canal some 24 hours, during which digestion and absorption of copper would go on, *Cameron*, 2561-62.

## 61d. PRESERVATION :

For three months would be useless for trade purposes, *Copeman*, 1236-37.  
No change in greening of peas in last 18 years, *Copeman*, 1246-47.  
Different treatment in France as regards copper of peas for home use and for exportation, *Copeman*, 1249-52.

## 61e. UNCOLOURED :

Used brown in Germany generally, *Copeman*, 1232.  
Used stewed *au naturel* in parts of France, *Copeman*, 1232.

## 62. PENETRATIVE POWER :

## 62a. BORACIC ACID :

Some, *Prossor*, 592-93.  
Nil, as to bacon, *Gregson*, 898-99.  
Would permeate hung hams, *Davidson*, 1588-89.  
Hams penetrated would not be sold as fine meat, *Davidson*, 1588-89.  
Should not be used for hung meats, *Davidson*, 1615-19.  
Has been known to penetrate an inch into moist meat, *Davidson*, 1590, 1592, 1611-12.  
Penetration of meat tested by smell, *Davidson*, 1604-8.  
Found pervading whole ham, *Hill*, 2356-57.  
Hams found to be cured with borax, with from 4 to 24 grains per lb. in the meat, *W. C. Williams*, 5176-77, the meat having been penetrated, 5178, some of the meat being foreign, 5179; and bacon found to be penetrated by borates, 5180.  
If it does not get into the meat no harm done, *Harris*, 5962. No experience of the practice, 5964, nor of the trade, 5966.  
Penetration of meat by sprinkled borax demonstrated by experiments, *Harris*, 5968-78, 6019-27.

(See also under Bacon, Danish.)

## 62b. BORACIC ACID : Game :

Does not penetrate, *Hudson*, 520.

## 62c. BORACIC ACID : Meat :

Does not penetrate, *Hudson*, 520.

## 62d. BORAX : Bacon :

Slight, if any, *Kellitt*, 17, 18, 36-38.  
Does not penetrate, *Bennett*, 140, 148.  
Penetration possible if large amount used for long contact with meat, *Bennett*, 152-55.

## 63. PEPPER :

Not foreign to the animal body, *McFadyean*, 1800.

## 64. PERCENTAGES OF FOODS PRESERVATISED :

## 64a. BUTTER :

In 44.5 per cent. of samples examined in Cardiff, *Walford*, 1841.  
Some 26½ per cent. of samples examined in 1899, in County Glamorgan, *Williams*, 2126.  
In 28 per cent. of samples examined in Birmingham in 1896-99, but varying seasonally and locally, *Hill*, 2344-48, 2385, 2472-74.  
Dr. Dyer found 30 of 234 butter samples boracised, *Fisher*, 4717-21.  
Probably three-fourths of imported butter preservatised, *Hehner*, 5616-19, 5631-33.  
Ninety per cent. of numerous samples, *Hehner*, 5564-65.

64. PERCENTAGES OF FOODS PRESERVATISED—*continued*.

## 64b. MILK, BORACISED :

Some 8 to 13 of total samples in Cardiff, *Walford*, 1829-30.  
In 1896 in Birmingham, 8.3 per cent. of samples, *Hill*, 2334.  
Dr. Dyer found only one of 270 samples boracised, *Fisher*, 4717.  
In skim milk and separated milk borates found more than in new and unadulterated milk, *W. C. Williams*, 5149-54, 5300, 5392.

## 65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES :

## 65a. BORACIC ACID : Albuminuria :

Temporary, *Wild*, 1447.  
Three cases known, *Wild*, 1462.

## 65b. BORACIC ACID : Digestion :

Interfered with, even by small doses, *Walford*, 1856-60, 1863-64.  
Effect in food on digestive ferments studied, *Cripps*, 1936-39, 1974.  
In 1 per cent. solution, no detrimental influence on salivary digestion, *Cripps*, 1940-44, 1948.  
No retarding influence on peptic digestion, *Cripps*, 1944-47.  
No retarding influence on rennet ferment, *Cripps*, 1952.  
Action of borax and of boracic acid different, *Cripps*, 1949.  
Using zymine as a digestive agent, slight retarding influence shown on digestion of strong boracic acid solution, *Cripps*, 1952.  
As used in butter and cream no ill-effect produced, *Cripps*, 1958.  
Decomposition of food in stomach retarded, *Bond*, 3135-37, 3140, 3142.  
Has little effect on food, *Foulerton*, 4160.  
Boracic acid peppered on fibrous food at meal times, *Attfield*, 6502, 6513-15. No bad effects on digestibility of food noticed, 6503-4, rather the reverse, 6505-6, 6512.  
Action of certain bacteria inhibited, 6507-9. Stomach washed out and contents examined, 6502, 6510-11. Nothing much to be learned from bacteriological examination of the contents, 6516-19.

## 65c. BORACIC ACID : Eruptions :

In an adult patient taking 30 grains per diem, *Wild*, 1422-27.  
No evidence of skin eruptions from antiseptic use of the acid, *Anderson*, 7192.

## 65d. BORACIC ACID : Excretion :

By kidneys as an alkaline salt, and free boracic acid, according to dosages, *Wild*, 1419.  
Through the kidneys, *Attfield*, 6501, how much daily not known, 6502.  
Boracic acid excreted by the kidneys, *Hutchison*, 6706.

## 65e. BORACIC ACID : Nausea :

Resulted from 120 grains taken in four hours, *Wild*, 1418.  
Said to have been caused by 5 grain doses, *Stevenson*, 4821.

## 65f. BORACIC ACID : General Physiological Effects :

Upon the system, should determine the question of its use as a preservative, *Cripps*, 1952, 1954-55, 1959.  
Different modes of administration, as a drug and in food, may account for divergent action on man, *Williams*, 2199, 2200.  
Use in foods risky, *Handford*, 2281-82.  
Some people continue use notwithstanding unpleasant effects, *Handford*, 2266.  
Unpleasant effects come and go as it is used and disused, *Handford*, 2266.  
Poorer classes may suffer from the acid without seeking medical aid, *Cameron*, 2583-84.  
Effect on infants only, to be judged by experiments on kittens, *Annett*, 2666.  
Effects on adults probably idiosyncratic, *Annett*, 2666.

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued.*65f. BORACIC ACID: General Physiological Effects—*continued.*

Studied, *Bond*, 3063.

Not necessary to know that drug was being taken by patient in food, but would like to know it, and fact of any drug being taken in a way to modify treatment prescribed should be known, *Bond*, 3067-69, 3074.

Drug not unsuitable for children, *Bond*, 3073.

Borax-packed bacon not known to have been harmful, *Bannister*, 3494.

Has little effect on digestibility of food, *Foulerton*, 4160.

Physiological action of boracic acid is to cause a certain amount of skin eruption, *Tubb-Thomas*, 4931. Medical profession generally ignorant of the injurious effects of boracic acid. Evidence in the pamphlet of the Boric Syndicate not altogether satisfactory, 4938-39. Harm held to result from administration as a drug too soon after food, 4939-40, and indiscriminate use objected to, 4941, as well as use unknown to the consumer, 4942.

Borax or boracic acid or both mixed in quantity just sufficing to preserve milk would probably be harmless to the majority of people up to four or five pints daily, *Hutchison*, 6759.

Borax and boracic acid studied as regards children, *Still*, 6784-86. In cases of  $2\frac{1}{2}$  grains of each to a pint of milk looseness of bowels has resulted. In another case distinct benefit accrued. Has given  $2\frac{1}{2}$  grains of each three times a day for epilepsy to older children, with good effect, when added with bromide, but looseness of bowels has in cases resulted, and in one instance the boracic acid had to be stopped, 6787-88.

## 35g. MILK, BORACISED: General Physiological Effect:

No harmful results known, *De Hailes*, 3976-81.

As used, harmless to ordinary individual, but probably hurtful in cases of infants and invalids; but  $\frac{35}{1000}$ , 35 grains per gallon, would be safe for an individual taking a pint daily, *Foulerton*, 4047-49.

## 65h. BORACIC ACID: Affirmed Physiological Effects:

Alleged in a delicate lady, *Jones*, 1317-19, 1323-27, 1349-60, 1386-90.

Poisoning by, produces diarrhoea, vomiting, low temperature, and may much resemble chronic ptomaine poisoning, *Jones*, 1332-36.

Slight disturbance from continued doses of 15 to 20 grains, *Wild*, 1418.

In  $\frac{1000}{1000}$  in milk would result in loss of appetite and nutrition in baby, if continued, *Wild*, 1433-35.

Eruption and loss of hair, in 30 grain doses daily, *Wild*, 1422-27.

All results known from 10 grain doses, *Wild*, 1461-62.

Held to be detrimental to health, *McFadyean*, 1764-66.

Continuous daily doses of 30 grains would have ill-effect, *McFadyean*, 1770.

Long experimentation would determine the produced effect, *McFadyean*, 1796-97.

Though unobserved may be none the less, injurious, *McFadyean*, 1798-99.

Inferential, *McFadyean*, 1775.

Objectionable because of unknown effect, *McFadyean*, 1802, 1815-16.

Interferes with digestion even in small quantities, *Walford*, 1856-60, 1863-64.

Held to have caused injury in food, *Williams*, 2112.

Absence of proof of injury in food may arise from failure of observation, *Williams*, 2196-98.

In internal use, an irritant, and causes loss of appetite, *Handford*, 2264-65.

Gastric disturbance has followed use in cystitis, *Handford*, 2285-87.

Evil results from borax-dusted meat, *Handford*, 2280.

Marked and hurtful, even fatal, *Hill*, 2339.

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued.*65h. BORACIC ACID: Affirmed Physiological Effects—*continued.*

Inconvenience from preservatised food has arisen on many occasions, *Hill*, 2372.

Hearsay instances quoted, *Hill*, 2373, 2423.

Injury has followed internal use, *Hill*, 2421-22; *Mann*, 2607.

Indiscriminate use dangerous, especially as regards infants and invalids for whom it might be medicinally required, *Cameron*, 2535.

Injury has followed external use, *Mann*, 2607.

Injurious effects on infants held to be decided in amounts used on kittens, *Annett*, 2651-52.

Thirty grains per diem known to have produced severe symptoms, *Annett*, 2667.

Continued dosage harmful, *Boyce*, 2776.

Itching of skin in a few cases in dropsical old men with renal disease, *Bond*, 3083.

Thirty-grain doses daily would create pronounced skin itching and perhaps some eruption, *Bond*, 3087.

Injury held to have followed external use, *Robinson*, 3304.

Child taking 160 grains a day, as is possible in milk, would be injuriously affected, *Blyth*, 3467.

Prejudicial to children's health, *Bannister*, 3658.

Rash known to be produced by 20 grains, *Rideal*, 3692.

Nausea said to have been caused by five-grain doses, *Stevenson*, 4821.

Boracic acid as a preservative deleterious, *Kaye*, 5502. Dangerous to take 54 grains, 5506. Presumptive evidence obtains as to prejudicial effects of the acid, 5513.

Harmful effects of borax and boracic acid as medicines vouched for on much evidence, *Starling*, 6944. Infantile scurvy might be produced by borax, 6945. Unlikely that borax taken continuously can be other than harmful, 6955.

Boracic acid prescribed by witness, *Anderson*, 7186, 7210, and its effects observed, 7187.

From 30 to 60 grains daily for bladder disease have frequently caused dyspeptic disturbances sufficient to cause misery, the symptoms quickly subsiding on the acid being given up, 7188. Serious dyspeptic trouble likely to accrue to child taking 10 grains a day in milk, 7204.

Milk preservatised known in a few cases to have caused derangement, *Womack*, 7474. A small amount of boracic acid in milk has caused digestive disturbance in individuals, 7475-77.

Borax and boracic acid have caused skin eruption and dyspepsia, *Halliburton*, 7541-49. Borax more readily soluble than boracic acid, 7543. Admixtures of both commonly used in the form of glacialine, 7544. Harmfulness of continued use of borax on kidneys held; mal-nutrition of infants fed on boracised milk instanced; digestibility of milk interfered with by minute doses of borax, but not of boracic acid, 7545, 7548.

## 65j. MILK, BORACISED: Affirmed Physiological Effects:

Milk treated with boracic acid by a dairymen, and also with "glacialine" containing as its basis boracic acid by the cook, held to have led to serious illness of five of seven inmates of a house, the two who had not participated in the milk escaping. Milk taken alone, blended with tea, or in blanc-mange. Symptoms were vomiting, colic, suppression of urine, and great prostration. Of nine fowls which took the blanc-mange five pullets, which ate voraciously, died, *Robinson*, 3301, 3345; amount of milk taken by sufferers not known, 3342-43, 3346-47; the two inmates who escaped had a little milk in tea or coffee, 3314-16; crop and gizzard of fowl and the milk examined; blanc-mange not examined; boracic acid

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued.*65j. MILK BORACISED : Affirmed Physiological Effects—*continued.*

held to have caused the illness, 3302; quantitative analysis of milk not made, 3303, 3305; boracic acid in large quantity found deep seated in fowl, 3303, 3344; symptoms such as would be expected from borax or boracic acid, 3304; all possible factors other than boracic acid eliminated as cause of illness, 3305, in the house in Dover, 3306; blanc mange deemed the cause of the illness, 3313; milk and blanc-mange both implicated, 3317; latter made of ground rice, eggs, sugar, boiled milk and vanilla flavouring, 3318-19; and the contained milk held to be special factor, 3320; but some other constituent may have been in question, 3321. Farm furnishing the milk visited, 3322; boracic acid added to the milk by the milkman, 3323-26; this and the added glaciale doing the harm, 3327; the milk would be consumed in other houses, but not known to have had glaciale also, 3328; and in this respect would differ, 3329; possibly, 3330-31.

Quite possible that cases of infantile diarrhoea and enteritis in the town may have had relation with the particular milk supply, 3332-33; possibility of preservatised milk having relation with infantile diarrhoea almost a conviction, 3334.

Dover poisoning by boracic acid not accredited, *Rideal*, 3778-80.

Case of illness of a child after one day's boracised milk diet, *Hope*, 6841, 6910-12.

Harm to infants from boracised milk known of, *Starling*, 6956.

65k. BORACIC ACID : Negative Physiological Effects : Continued doses taken without ill-effect, *Prosser*, 571, 574-81, 599-606.

No ill-effects heard of, *Trengrouse*, 702; as regards meat, *Gregson*, 915; *Sinclair*, 947 *Jones*, 1314, 1316.

Family use of boracised milk and butter large and continuous, *Lovell*, 809-15.

No ill-effects personally from 10-grain doses, *Wild*, 1416-17.

None from 5-grain doses, *Wild*, 1459-60.

None from single 30-grain dose by adult, *McFadyean*, 1768.

Thirty grains taken by some persons daily for long periods with seeming impunity, *Handford*, 2266.

Use in stomach not known to have caused ill-effects, *Handford*, 2284.

Beneficial when used medicinally in moderate doses, *Bell*, 2786; extreme instances of life saving by 30 grains daily, 2787, 2789; borax constantly sucked for years without ill-effect, 2787; no ill-effects would follow consumption of boracic compounds by community unknowingly, 2788; neither 40, 50 nor 90 grains daily dangerous, 2790-91, 2811, 2824-25; in a surgical case, with great absorption into system, several pounds used on raw surface without ill-effect, 2793-94; no ill-effects have followed absorption, 2796; no ill-effects from use known, 2834-36.

No ill-effects have followed use for months in bladder diseases, *Bond*, 3065.

No ill-results from external use, even in extreme case, *Bond*, 3097.

Harmless as used as a preservative, *Bond*, 3088.

Boracic acid taken by witness, 20 grains a day, for a fortnight continuously on full stomach produced no observed ill-effect at all, *Hutchison*, 6693-94, 6696-97; if witness has a weak spot it is his stomach, 6695; also 5-grain doses twice daily of borax and boracic acid solution, 2½ grains of each, for the same period had no ill-results, 6698-6700, 6712; inference that boracic acid or borax as used in milk consumed by an adult would be harmless to an average healthy man, 6701.

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued.*65k. BORACIC ACID : Negative Physiological Effects—*continued.*

Harmful results of continued use of borax

boracic acid read of, *Hutchison*, 6702; no bad effects noticed when borax used for short period for epilepsy, 6703; it was mixed with bromide; not known which did the good, 6704; might be dangerous to children to take 30 grains daily in milk, 6715-16; would not like to administer 80 grains of boracic acid in a pint of milk, but could not say it would produce ill-results on gastric cells, 6753-54; *Leibreich's* experiments known as to borax, boracic acid, and formalin, 6755; showing surprisingly little local effect on lower animals, 6756; adult dogs chiefly, 6757; and inference on puppies cannot be inferred therefrom, 6758. No practical experience of harm from boracised food, *Anderson*, 7203.

## 65l. BORACIC ACID : Poisonous Properties :

May arise from idiosyncrasy or kidney disease, *Wild*, 1463-66.

No cases known or heard of, *Walford*, 1867-69; *Hill*, 2415.

Unquestioned, *Williams*, 2195.

Studied experimentally, *Rideal*, 3680.

## 65m. PRESERVATIVES : General Physiological Effects :

Injury to health cannot be proved, *Williams*, 2133-34, 2183-86.

Not known to be injurious to health, *Williams*, 2146.

Injury to health may certainly arise, *Williams*, 2149-51.

Question of injury based on experts' statements, *Williams*, 2180-81.

Digestive disturbances not clearly defined, *Annett*, 2697.

Immunity as the result of repeated dosage an argument against preservatives, because of expense at which gained, *Boyce*, 2735-36.

Digestibility of food inappreciably affected by  $\frac{500}{1000}$  of formaldehyde or  $\frac{200}{1000}$  of borax and boracic acid mixture, *Rideal*, 3681-86, 3772-76.

Objections to preservatives lie in their chemical character, and action *quâ* decomposition of food in the human economy, *Faber*, 4205.

Injurious effects of preservatives on digestion inferred, *Long*, 4579. Salicylic acid held to arrest peptic digestion, and heavily boracised milk, 210 grains per gallon, to be injurious to a milk drinker, 4613, 4696. Illness alleged to be caused by preservatised milk, 4615-26. Preservative drugs in food objected to, 4627. Good deal of injury by preservatised food suspected, 4628.

If medical men were aware of the substances used as preservatives and the extent to which used, mischief thereby would be looked for, *Tubb-Thomas*, 5011. Parallelism of lead poisoning and ergotism, 5012-13.

Should be proved harmless if permitted to be used, *Corfield*, 5124-27.

Physiological experiments point to injurious effects of preservatives, *Kaye*, 5514-15, especially as to formalin, 5516-17. Preservatives to be effective must injuriously affect human delicate digestive organs, 5518, 5547-52. Boracic acid as a drug and as a preservative daily in use very different, 5552.

Physiological action of modern preservatives studied, *Attfield*, 6495, as used by witness for personal dyspepsia under medical advice, 6496.

Retardation of digestion of salted and smoked foods not due to antiseptics, *Attfield*, 6520.

Inhibitory action of preservatives on bacteria of decomposition and therefore also on digestion not true in witness's judgment, *Attfield*, 6546.

Continued use of a preservative might have tendency to diminish vitality of human body, *Starling*, 6987.

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued*.65m. PRESERVATIVES: General Physiological Effects—*continued*.

Relative value and harmfulness of preservatives need to be accurately ascertained, *Brunton*, 7431, over a length of time as to result of their continued use, 7432-36. Many of the preservatives may be as harmless as chicory in small quantity, but not in excessive quantity, 7442.

No evidence of ill results in St. Bartholomew's wards from small doses of preservatives, *Womack*, 7502, 7523-24. No good results reported, 7503. Staff generally hostile to preservatives, 7504, 7508, and against their indiscriminate use in food, 7505-6.

Physiological experiments form the basis of evidence to be given, especially as to boron compounds and formaldehyde. Continuous use of antiseptics objectionable on general principles, *Halliburton*, 7528. Even salt immoderately used has been injurious, 7529-30. Germicidal substances hostile to man in food, 7528-30.

## 65n. PRESERVATIVES: Affirmed Physiological Effects:

Might be distinctly injurious if of germ restraining power, *McFadyean*, 1752.

Proof would render them indefensible, *Walford*, 1872.

Held to be injurious, *Vasey*, 2101-6.

Prejudicial to digestive processes, *Hill*, 2511, 2515-17.

Haphazard administration most dangerous, *Hill*, 2518.

Interfere with digestive properties, *Cameron*, 2533, 2563-69.

Some undoubtedly injurious in themselves; some probably so; some retard or prevent digestion, *Mann*, 2604-5.

They inhibit the action of enzymes, *Mann*, 2617-19; *Annett*, 2697.

Digestive properties of food would be injuriously affected by effective preservative drugs, *Cassal*, 3813, 3872.

Digestibility of food must be inhibited if preservatives are effective, but experiments do not bear this out, *Corfield*, 5093-96.

Digestion at times affected by preservatives, *Grünbaum*, 6479.

Harm may accrue to young infants by use of preservatives milk, by way of retarded digestion. Kitten experiments demonstrate harm by boracised and formalised milk, *Hope*, 6830. A case of illness in a child by one day's boracised milk diet, 6841, 6910-12. Very serious harm will result to infants if the "humanised" milk now sold as pure milk is preservatives, 6879, and this may result despite practicable precautions, 6880-83. Harm looked for if boracic acid administered in scarlet fever and kidney disease, 6893. Harm to infants from preservatives difficult to trace, 6908-9. Relation of preservatives to infantile diarrhoea not traced, 6922.

Preservatives in certain cases harmful, and want of fresh food harmful to health of community, *Poore*, 7340. Scurvy follows prolonged use of preserved food, 7341, 7414-17. Food chemically preserved might be positively harmful, 7342; but ignorance at present obtains as to the action of chemical preservatives, 7341, 7349. No reason why chemical treatment of food should not be innocuous, 7421-22. Preserved vegetables have failed to prevent scurvy, 7343. Scurvy decreasing by reason of added precautions, 7344. Even preservatives lime juice has failed as an anti-scorbutic, 7345.

## 65o. PRESERVATIVES: Negative Physiological Action:

No ill-effects known, *Boseley*, 1047-48.

## 65p. FORMALIN: General Physiological Effects:

No experiments made, *Boseley*, 1001.

Opposed to life, *McFadyean*, 1792-95, 1806-10.

Inference from Chittenden's experiments in dogs in normal health, that no harm would

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued*.65p. FORMALIN: General Physiological Effects—*continued*.

accrue to adults from formaldehysed milk, *Boyce*, 2733-34.

Non-irritation at a manufactory would speak well for modern methods employed, *Boyce*, 2771.

Formic aldehyde used in bladder diseases in 10-grain doses thrice daily, as a preparation of formic acid and ammonia, called "urotropine," *Bond*, 3123-29, 3132-34.

Potency and action inside the body not known, *Brierley*, 3216-17, 3223-28.

Hardening effect on fish not known, *Brierley*, 3231.

Rideal quoted as showing less interference with digestion by formalin than by boracic acid or alcohol, *Brierley*, 3219.

Dangerous, acts directly on milk curd, is a poison, and an antiseptic, *Bannister*, 3659-60.

Negative evidence not of much worth in face of positive evidence, *Cassal*, 3833.

Formic aldehyde would perhaps render milk a little less digestible, *Foulerton*, 4047-49.

Use for persons on milk diet injurious, but not for ordinary persons, *Foulerton*, 4146.

As a preservative has but little effect on digestibility of food, *Foulerton*, 4160.

Formalin in milk in very small doses as affecting the organism, not known of, but harmful properties suspected, *Fisher*, 4729-31, 4738.

Effect on peptonised milk for invalids suggested as matter for inquiry, *Fisher*, 4743.

Hardening effects of formic aldehyde known, and dangerous properties pointed to, *Fisher*, 4754-60, 4765-66.

Affects digestion, *W. C. Williams*, 5216-17; in milk, *Richmond*, 5652-58.

Kills micro-organisms, *Richmond*, 5742; in relatively strong solutions, 5748; and is a disinfectant, 5744.

Local irritant, *Hutchison*, 6741.

Harmful results may accrue from formalin as a preservative, but no considerable harm probably, *Still*, 6816. It would interfere with digestion if long continued. Chary of letting children have anything containing it, 6817.

Formalin takes away food character of proteids, *Starling*, 6939. In 1:1000 formalin stops the action of pancreatic juice, 6963; not tested as to 1:10000, 6964.

Objections to formalin based on experiments showing its effect upon proteid and digestive activity, *Starling*, 6965-66.

## 65q. FORMALIN: Affirmed Physiological Effects:

Held to be injurious, *Lovell*, 806.

Renders food indigestible, *Voelcker*, 1817.

Retards digestion of food, *Mann*, 2607. Experiments show arrestive action on pancreatic ferments, *Mann*, 2619. A blood poison in large doses, *Mann*, 2629-32.

Injurious effects on infants regarded as decided in amounts used on kittens, *Annett*, 2651-52.

In milk, inferred, even in small proportion, *Boyce*, 2724-25. A great irritant, its action inhibitory; lowers the cell vitality, has direct action on enzymes, and affects digestion by way of food, *Boyce*, 2751-52, 2754-57.

Raw, has a hardening effect, on certain tissues, but in quantity used, 0.012 per cent., effect infinitesimal, *Brierley*, 3220-21.

Hardening effect stated on foodstuffs would if appreciable affect their digestibility, *Brierley*, 3232-35.

Dangerous substance even in small amount, injuriously affecting digestion, and having very hardening properties, *Cassal*, 3831-32.

Digestive properties of food would be affected injuriously by any quantity sufficing to preserve milk, *Cassal*, 3873-74.

Injurious if taken continuously, *Tubb-Thomas*, 4978.

Personal experiment, 1:1000, resulted in illness, *Hehner*, 5612-13.

65. PHYSIOLOGICAL EFFECTS OF PRESERVATIVES—*continued*.65q. FORMALIN: Affirmed Physiological Effects—*continued*.

Formalin not known from physiological point of view, *Womack*, 7483-84, but its indiscriminate use objected to, 7485, as interfering with digestibility of food, 7486. It might act on secreting power of cells, 7489. It is a hardening substance, 7490, and its use should be limited, 7491. Objected to by St. Bartholomew's medical staff in milk and butter, 7500-1. Formic aldehyde for hardening substances used in much higher proportion than as a preservative, 7513-15. The compound formed with proteids by formic aldehyde will be indigestible, 7516, and the formic aldehyde would render milk indigestible, 7517-18, and should be largely under restriction, 7519.

Formaldehyde a marvellous antiseptic and inhibitive of digestion in minute quantities, *Halliburton*, 7548. Is absolutely opposed to its use, 7572; and the indigestibility of food by its use held to be proved by experiments *in vitro*, 7583-85.

## 65r. FORMALIN: Negative Physiological Effects:

Family have used formaldehysed milk for two years without injurious effect, *Brierley*, 3229, 3255.

## 65s. SALICYLIC ACID: General Physiological Effects:

Thirty grains in alcohol less harmful than the alcohol, *Bond*, 3119-22.

Injury to individuals may result from indiscriminate use of salicylic acid, *Stevenson*, 4810.

Non-injury of many not conclusive of non-injuriousness, *Stevenson*, 4824-25.

Salicylic acid stops the action of certain enzymes, *Richmond*, 5745-46.

Salicylic acid is less harmful than formalin, but is apt to cause stoppage of gastric digestion in the stomach, *Starling*, 6941. It is a potent drug, and should not be used unknown in food stuffs, 6942.

Little known to witness, *Halliburton*, 7571.

## 65t. SALICYLIC ACID: Affirmed Physiological Effects:

Used medicinally, acts powerfully on liver; is a depressant, usually taken in form of salicylate of soda; in large doses produces weakness and sickness; sometimes causes poisonous symptoms, *Cameron*, 2546.

Causes internal disturbance if in cider persistently consumed, *Mann*, 2611.

Delirium as caused by, not known, *Bond*, 3107, 3110-11.

Affects individuals injuriously, *Stevenson*, 4823.

Used externally, irritates, and a most undesirable substance in food, *Corfield*, 5073-74. People ought to know they are taking it, 5075; continuous use possibly cumulative, 5076-77; and hence more seriously effective, but acquired immunity possible, 5078-79.

Salicylic acid, as salicylate of soda, produces distinctly unpleasant symptoms, *Anderson*, 7211-12.

## 65v. SALICYLIC ACID: Negative Physiological Effect:

No ill-result with 10-grain doses, *Bond*, 3105-6.

Given in bladder diseases, *Bond*, 3107.

Suits witness for gout, *Robinson*, 3340.

## 66. POISONS:

Not defined by statute in relation to foods, *Cassal*, 3789-94.

## 67. PRESERVATIVES:

## 67a. COMPOSITION:

Examined, *Voelcker*, 1636-39, 1652.

Foreign to the body, *McFadyean*, 1756, 1778-81.

Five, listed, were compounds of borax and boracic acid, or pure boracic acid, *Kaye*, 5455-57.

67. PRESERVATIVES—*continued*.67a. COMPOSITION—*continued*.

Always boric compounds found in butter, *Hehner*, 5566.

Preservatives in general use principally boric compounds, *Richmond*, 5643. Analysis handed in, 5644-45. Salicylic acid, soda and magnesia in a glycerine solution also in question in two samples of preservatives, 5545. Formaldehyde also used, 5647. Difference between boracic acid, formic aldehyde, and salicylic acid in dilute solution, one of degree, but in strong solution, one of kind, 5747. Fluorides not found, 5749. Hydro-fluoric acid in large quantity found experimentally to be the most perfect preservative for milk; and fluoboric acid extremely strong preservative, 5750; data promised, 5751-52.

## 67b. CURE:

Not effected in meats, apart from salt and saltpetre, *Davidson*, 1586-88, 1610.

## 67c. DISTRIBUTION:

Unequal, a barrier to standardising, *Vasey*, 1999-2001, 2003.

## 67d. FOREIGN LAW AND PRACTICES:

Continental legislation as to food inquired into, *Grünbaum*, 6407; principally in Germany and Austria, 6408; as to preservatives in food, 6409.

## 67e. AMERICA:

Prohibition of preservatives in milk absolute in New York State, *Hill*, 2452-53.

## 67f. AUSTRIA-HUNGARY:

Prohibition of preservatives in milk absolute, *Hill*, 2454.

Prohibition of boracic acid in force in Austria, *De Hailes*, 4006; also salicylic acid, *Corfield*, 5098-5100.

Prohibition of preservatives believed to exist in Austria, *Boyce*, 2745.

Vienna has bye-laws prohibitory of preservatives in food, milk being especially in question, and sodium carbonate being included in the prohibition, *Grünbaum*, 6421-22, 6464. Ministerial decrees in Austria prohibit specified preservatives and colouring matters, 6426-27. All preservatives are prohibited in milk, and Hungary is seeking to prohibit all preservatives, 6428. Present action in contemplation in Austria not known, 6429-30. In Vienna only one sample of milk in one year found to be preserved, and that by a large quantity of sodium carbonate, 6463. Preservatives forbidden in beer in Austria, 6468-69. No evidence as to use of saccharin procured, 6475.

## 67g. BELGIUM:

Prohibition of preservatives in milk absolute, *Hill*, 2454.

Preservatives prohibited, *Boyce*, 2741-42.

## 67h. CANADA:

Prohibition of preservatives in force, *Riley*, 819.

## 67j. DENMARK:

Saccharin in wine and beer allowed only if declared on label, *Faber*, 4206.

Prohibition of salicylic acid, boracic acid, and certain mineral salts in wines and spirits in Denmark, *Faber*, 4206, including salts of aluminium, barium, strontium, and magnesium, 4207. Salicylic acid prohibited since 1886, 4208. That and boracic acid prohibited as injurious to health, 4208-9, 4266, 4354-56, it being felt also easier to prohibit borax in butter prior to its use becoming general, 4267, and thus probably dangerous by use in many articles of diet, 4268-70. Only common salt allowed in dairy produce in Denmark, and no inconvenience results, 4210-11, even in Copenhagen, 4212-15. Prohibition of borax in butter had rather a present element of injury to trade, though a probable prospective advantage, 4271-75.

67. PRESERVATIVES—*continued.*

## 67k. FRANCE :

Regulation strict, *Hudson*, 521-22.  
 Prohibition of preservatives enforced on American bacon and ham, and withdrawn in 1899, *Hudson*, 505, 523.  
 Prohibition of boracic acid in butter used in France, *Williams*, 2218-20; *Hehner*, 5619-22.  
 Butters exported from France are preserved, *Williams*, 2218-20; *Richmond*, 5684.

## 67l. GERMANY :

Preservatives prohibited, *Boyce*, 2741-42.  
 Prussian ministerial circular totally prohibitive of preservatives in food, *Grünbaum*, 6410; and local bye-laws made in the same sense. Preservatives in milk totally prohibited, 6411, 6413-14, 6432; as also in wines, 6411-12. Milk dealt with on account of impossibility of fixing standards for the kingdom, 6415; and because harm from use of preserved milk was feared, 6433-34; especially as to children, 6435. Proceedings taken at Hamburg and elsewhere as to preservatives in milk, 6416-17; and as to sodium sulphite in minced meat, 6418; the substance being injurious to health in small amount, 6419-20. Germany seeking to prohibit preservatives in meat, 6423. Experiments were made as a basis for existing legislation, 6436-38, 6442, 6465. Formalin used, but very rarely found, 6439; the same as to salicylic acid, 6440; as regards milk, 6441. Expert evidence has been taken in Germany as to results following the administration of sodium sulphite, 6442, 6445; namely, headache, diarrhoea, indigestion, and catarrh, 6446; even in small doses, 6447. Found in minced meat, a food for invalids, from 0.08 to 0.86 per cent.; not found in milk, 6444-45, 6447. Medical profession against preservatives, 6457-58; on general principles, and as not knowing when patients were taking them, 6459. Berlin milk supply unpreserved, 6459-62. Distribution in closed vessels, 6470-72; and in bottles in the smaller towns, 6473-74. Evidence as to preservative legislation mainly concerned with milk and minced meat, 6466. Preservatives forbidden in beer in Germany, 6467, 6469. Milk sent by rail in ice-cooled vans, 6477.

## 67m. NORWAY :

No law known against use of preservatives in butter, *Lovell*, 755-58.  
 Practice as to preservatives not known, *Faber*, 4312-15.

## 67n. SWEDEN :

No law known against use of preservatives in butter, *Lovell*, 755-58.  
 Practice as to preservatives not known, *Faber*, 4312-15.

## 67o. SWITZERLAND :

Prohibits borax and boracic acid in imported meat, *Grünbaum*, 6423-25.  
 Prohibition of preservatives in milk in parts of the country, *Hill*, 2454.

## 67p. MEDICAL PROFESSION :

Medical profession do not regard preservatives in food seriously, *Hutchison*, 6727; nor do the hospitals, 6728. Physicians practice not stultified by preserved milk, 6729; unless boracic acid were both prescribed, and also in the patient's milk, 6730; as also with salicylic acid, 6731. Medical profession affected in this sense, 6732-35. The uncontrolled use of preservatives would be a bad thing from medical men's point of view, 6736.

Indiscriminate use of drugs as preservatives might be of serious moment for medical profession, *Still*, 6806, 6810; especially as to salicylic acid, 6808-9; but borax and boracic acid rarely used, and formalin never used internally, 6807. Physicians should know accurately the amount of drugs taken in food, 6810.

Physician should know composition of milk taken by a patient, *Hope*, 6894. He might stultify himself, 6895.

67. PRESERVATIVES—*continued.*67p. MEDICAL PROFESSION—*continued.*

Use of preservatives of interest to medical profession, especially as to salicylic acid, *Starling*, 6967; in cases of rheumatism, for example, when results might prove to be very serious, if the amount taken also in food, 6968, 6970; salicylate of soda being in question, 6969.

Medical men should know if patients are taking drugs in their food, *Anderson*, 7197, 7204. Their position might be stultified, 7198. Harm caused by milk in one instance, 7198-7202.

Matter of preservatives an important one to medical profession, *Brunton*, 7456-57. Practice of physician might be stultified by their use, 7458-62. Present committee hardly in a position to give a pronouncement as to preservatives, 7466.

## 67q. POWER OF PRESERVATIVES :

Limited, and the fact important, *Vasey*, 2004, 2056-57.

## 67r. PUBLIC :

Not self-protected against, *Vasey*, 2065-66. Should be able to purchase unpreserved food, *Vasey*, 2003, 2052, 2078. Not generally aware of their use, *Cameron*, 2532.

## 67s. SUPPLY OF PRESERVATIVES IN BUTTER :

From Limerick chemists, *Sandes*, 98.  
 Obviate glutting the market, *Shanahan*, 413-14.

## 68. PRESERVATIVES, USE OF :

## 68a 1. BORACIC ACID :

For meats, ham, bacon, sausages, herrings, &c., *Hehner*, 5623-27.

## 68a 2. BORACIC ACID : Bacon :

Dusted over mild-cured meat, *Prossor*, 563; *Davidson*, 1588-89.  
 Used during salting, *Prossor*, 556, 569.  
 Washed off after cure, *Prossor*, 556, 569, 590-91; *Davidson*, 1588-89.  
 Retained, 7 to 10 days, till cure complete, *Prossor*, 582-87.  
 Not advocated, but demanded, *Greyson*, 903.  
 After cure, *Davidson*, 1588-89.  
 By external rubbing or laying on, and so also in ham, *Hill*, 2354-55.  
 Borax packing used in American and Canadian bacon trade, *Harris*, 5961.  
 Not personally objected to, *Harris*, 5980.  
 Much the larger part of bacon coming to English consumer is borax-packed, *Harris*, 6018.

## 68a 3. BORACIC ACID IN BUTTER : Admixture :

Intimate, *Trengrouse*, 625, 628.

## 68a 4. BORACIC ACID : Butter : Detectable :

Flavour imparted only by large quantity, *Trengrouse*, 658.  
 Tasteless in small quantity, *Lovell*, 806.  
 Over 1 per cent., *Lovell*, 723, 983-89.  
 By taste, *Clement*, 1532-34.  
 Even  $\frac{1}{2}$  per cent., if butter be not keeping, *Clement*, 1535.  
 Not always, *Clement*, 1537-39.  
 One per cent. detectable, *Clement*, 1540.

## 68a 5. BORACIC ACID : Use in Butter :

Alone or blended, *Sandes*, 81, 82.  
 Basis of all preservatives, *Dale*, 243.  
 Called Preservitas, *Dale*, 271.  
 Mixed with the butter, *Dale*, 244, 251, 278-79, 318-20.  
 Dissolves in butter, *Dale*, 282.  
 Used to be added in solution, *Shanahan*, 349, 351.  
 Frequent, *Cameron*, 2527; *Cassal*, 3850-51.  
 Found in mixtures of margarine and butter, *Cassal*, 3852.  
 Used especially in summer, *W. C. Williams*, 5171.  
 Objected to, *W. C. Williams*, 5218-20.  
 Can be condoned only in annually diminishing quantity to vanishing point, *Hehner*, 5615.

68. PRESERVATIVES, USE OF—*continued*.

## 68a 6. BORACIC ACID : Milk :

Use decreasing, *Hill*, 2340, 2383-84.

May have reference to supply and demand, *Hill*, 2394-96.

In skimmed milk, *Hill*, 2364.

Unnecessary, *Hill*, 2461-66, 2470; *Cameron*, 2579.

Use frequent, *Cameron*, 2527.

Attitude of medical profession towards, will depend on the finding of the Committee, *Cameron*, 2583.

More frequent than formaldehyde, *Munn*, 2608-10.

Found in milk, *Annett*, 2636-39.

More beneficial than harmful, *Bell*, 2814, 2826.

Used by Glasgow Dairy Co., *Bell*, 2787.

More in summer than winter, *Blyth*, 3439, 3442.

Country milk not so treated 20 years ago, much London milk not treated now, but retail dealers in poorer parts create a difficulty, *Blyth*, 3454-57.

Unpreservatised milk should be procurable, *Blyth*, 3458.

Found in London hospital milk, *Cassal*, 3821.

Advocated as best and safest, *De Hailes*, 3916.

Recommended in "Applied Chemistry," issued nine years ago, *De Hailes*, 4041-43.

In Guy's Hospital milk on one occasion, *Stevenson*, 4798.

Milk of high class dairymen not so much boracised as "over-day" milk vendor, who may doctor milk already treated, *Tubb-Thomas*, 4932. Boron compounds also used in private houses, 4933.

Recklessly used, and trade by its use improperly carried on, *Tubb-Thomas*, 4942-46.

Most in winter, when milk valuable, *W. C. Williams*, 5157, but data few, and basis of statement not of much importance, 5197-5215.

Milk largely treated in summer, but free in winter, *Kaye*, 5444-46.

## 68a 7. BORACIC ACID : Milk : Admixture :

Not always intimate, tending to vitiate analyses, *Walford*, 1902-3.

Generally added by wholesale purveyor, farmer, or middleman, *Hill*, 2336-37.

Three separate additions may be made, *Hill*, 2338.

Saturated solution easy of uniform distribution, *Bell*, 2827-28.

Acid sold largely by chemists without instructions as to use, *Brierley*, 3214.

Some portion might contain overdose, *Bannister*, 3634.

## 68a 8. BORACIC ACID : Milk : Application :

Powdered borax, *Walford*, 1901.

## 68b 1. BORAX : Use as bacon preservative :

For last 20-25 years, *Kellitt*, 13, 14.

In increasing quantity in place of very salty American bacon, *Kellitt*, 15, 29, 33, 35.

Reduces excess of salt, *Kellitt*, 15, 73, 74.

Sprinkled only on shoulder of Irish and Danish bacon, *Kellitt*, 68-69.

Not noticed in English and Irish bacon as in Canadian, *Bennett*, 135.

For packing American and Canadian bacon, *Prossor*, 594, *Trengrouse*, 618.

Washed off on arrival, *Prossor*, 597; *Trengrouse*, 619.

For preserving bacon, after cure with salt and saltpetre, *Bannister*, 3484.

Essential, under present conditions of trade and demand, *Bannister*, 3495-3500.

## 68b 2. BORAX : Butter :

Washed with solution in France and Australia, *Bennett*, 194-98.

Boraxed wrappers for French butter, *Bennett*, 199.

Boraxed wrappers effective, *Bennett*, 202-3.

Boraxed wrappers advised even for Colonial butter, *Bennett*, 208, 214.

No mixture, *Bennett*, 200, 201, 209, 219-20.

No conditions stipulated as to French butter, *Bennett*, 210.

68. PRESERVATIVES, USE OF—*continued*.

## 68b 3. BORAX : Butter, Irish :

No mixture known, *Bennett*, 219, 220.

## 68b 4. BORAX AND BORACIC ACID :

Becoming more general, *Boseley*, 986.

Unknown to consumer, objected to, *Jones*, 1313.

Should not be used in food, *Walford*, 1826-27.

Increasing, *Walford*, 1854-55; *Brierley*, 3210-11.

May lead to lack of cleanliness, *Walford*, 1839.

Most frequently used, *Vasey*, 2037.

Utterly bad in principle in foods, *Williams*, 2112.

Varies with season, and greatest in hot weather, *Williams*, 2141-43.

Decreasingly found in food in County Glamorgan, *Williams*, 2239.

Most frequent preservative in foods which are decomposed, *Hill*, 2436-40.

Indiscriminate use in food hampers medicinal treatment by the medical profession, *Hill*, 2460.

Not to be compared with salt as a preservative, *Munn*, 2628.

Should be controlled as to quantity, *Bond*, 3088, 3112.

Found in a variety of articles, *Cassal*, 3816.

Used for dusting poultry, also used in sausages, up to recommended quantity, 80 grains per lb., *Tubb-Thomas*, 4938, 4973-74.

Boric syndicate pamphlet issued with one object in view, and is a collection of data, leaning one way, towards favouring boric compounds, *Tubb-Thomas*, 4989-92.

Should not be used in food unknown to consumers, *Corfield*, 5075.

Not a food, *Corfield*, 5081.

## 68b 5. BACON :

Packing keeps it mild, *Gregson*, 894-95.

To surface only, in a dry state, after cure, *Gregson*, 865-66, 891-93, 900-1.

Complaints have had relation only to incomplete removal in washing, *Gregson*, 874.

Practically all washed off here, *Sinclair*, 945.

## 68b 6. BACON, AMERICAN :

For 75 per cent. of meat, *Gregson*, 859, 876.

All washed off on arrival, *Gregson*, 867, 869-70.

Retention would flavour bacon, *Gregson*, 868.

## 68b 7. BACON, CANADIAN :

For 75 per cent. of meat, *Gregson*, 859, 876.

## 68b 8. BUTTER :

Has improved manufacture, *Shamahan*, 385-86.

None used by Armour & Co., *Trengrouse*, 651.

Does not conceal defects, *Trengrouse*, 655.

May be repeatedly added, *Trengrouse*, 659, 662.

Creamery butter not dosed twice, *Trengrouse*, 664.

Only known preservative, *Lovell*, 715.

These only answer all purposes, *Lovell*, 806.

Used in all imported butters, *Lovell*, 782.

Frequently, some home, some colonial, *Voelcker*, 1653.

Only preservatives found, plus salt, *Voelcker*, 1654; *W. C. Williams*, 5169-70.

## 68b 9. BUTTER, AUSTRALASIAN :

Australian washed with solution, *Bennett*, 194-98.

Rancidity obviated in Australian, *Bennett*, 199.

Two per cent. found in some Australian, *Trengrouse*, 647-48.

Requisite, *Trengrouse*, 653, 673.

Unsalted but with boracic acid, *Trengrouse*, 621-22.

Requisite to prevent rapid deterioration after removal from cold store, *Trengrouse*, 624.

Australasian butter imported from Australia with, and from New Zealand without, preservatives presumably, *Riley* 828-29, 832, 834-35, 837-38.

68 PRESERVATIVES, USE OF—*continued*.68b 9. BUTTER, AUSTRALASIAN—*continued*.

Requisite, *Clement*, 1503-5; *Voelcker*, 168 1720-22, 1730-32.  
Expected to contain, *Davidson*, 1593.  
Believed to contain, *Davidson*, 1597-98.  
Proportion boracised not known, *Voelcker*, 1684-85.

## 68b 10. BUTTER, FRENCH :

Washed with solution, *Bennett*, 194-98.  
Rancidity obviated, *Bennett*, 199.  
Comes in wrappers soaked in solution, *Bennett*, 199.  
No mixture, *Bennett*, 209.  
No conditions stipulated, *Bennett*, 210.  
Probably used, *Trengrouse*, 627.  
Found in solution in factory butter, *Boseley*, 958-63.  
Found in butter, *Boseley*, 1031-32.

## 68b 11. FOOD :

Both found, *Vasey*, 1987-88.

## 68b 12. MILK :

Added varyingly from 1000 to 10000, *Boseley*, 953.  
Utility of 10000 doubtful, *Boseley*, 954.  
Amounts above 10000 frequent, *Boseley*, 958.  
Objected to, *Jones*, 1313.  
Would retard commenced decomposition, *Jones*, 1366-69, 1374-75.  
Might prevent detection of commencing decomposition, *Jones*, 1369; *Wild*, 1481-83.  
Would not mask decomposed milk, *Jones*, 1370-73.  
In  $\frac{1}{3}$  would wholly retard decomposition, *Jones*, 1376-77.  
May safely be used in small amount save for infants or in kidney troubles, *Wild*, 1429, 1444.  
In small amount better than no milk or sour milk, *Wild*, 1440-41.  
Seasonal, *Wild*, 1484.

## 68c 1. FORMALDEHYDE IN FOOD : Use :

Raspberries known to be sprayed with formaldehyde, *Boseley*, 970.  
Increasing, *Vasey*, 2041; *Brierley*, 3210-11; in milk, *Hill*, 2349, 2383-84; and is a dangerous preservative, *Hill*, 2333, 2342, 2418-20, 2443.  
Never used in butter, *Hill*, 2350, 2439.  
Stronger than boracic acid and used in smaller amounts, *Hill*, 2386, 2441-42.  
Injurious effects not known, *Hill*, 2387, 2416-17.  
Not known of, *Cameron*, 2558.  
Not justifiable but possibly harmless in foods, only occasionally used, *Mann*, 2626-27.  
Used in a few samples of milk, *McCracken*, 2932.  
Recommended four years ago, 10000, *Cassal*, 3835-36.  
Largely used, *Richmond*, 5647-49; *Hutchinson*, 6740.  
Objection lies to the indiscriminate use of formalin, *Attfield*, 6567.  
Formaldehyde, a marvellous antiseptic, *Halliburton*, 7548. Commercial formaldehyde known to be used in milk in 2000, 7586-88.

## 68c 2. MILK :

Found in milk, skim milk and separated milk, *Cassal*, 3816.

## 68c 3. FORMALIN :

A 40 per cent. solution of formaldehyde, *Boseley*, 952; *Cassal*, 3831-32.  
Schering's solution in demand when boracising of food was locally prohibited, *Jones*, 1393.  
Should not be used in food, *Walford*, 1826-27.  
May have replaced boron preservatives, *Williams*, 2240-41.  
Used since and because boracic acid detected in milk, *Robinson*, 3311.  
Company vending formalin recommend 2000 for milk, but that they always advised use of limit of 20000 not known, *Foulerton*, 4082-85, 4107.  
Sold to trade in one, and used also in 40 per cent. solutions, *Richmond*, 5648.

68. PRESERVATIVES, USE OF—*continued*.68c 3. FORMALIN—*continued*.

Formalin has an extremely hardening effect on gelatine in strong proportions, *Attfield*, 6521-30, 6566; of 40 per cent. solution, 6531. As a constituent of food, action not known, 6567.

## 68c 4. FORMALIN : Dairy Products :

Frequently used, *Boseley*, 951-52.  
Equally general with borax, *Boseley*, 989.  
Has preserved several samples of milk, *Boseley*, 990. Amounts used experimentally in milk, 2000 to 10000, *Boseley*, 992, 995. Amounts generally used in milk unknown, *Boseley*, 993. Minute traces found, *Walford*, 1840.  
Persists in milk, *Boseley*, 994.  
Formalised milk gives reaction with litmus paper, *Boseley*, 998-99.  
Renders milk indigestible, *Voelcker*, 1817.  
Found in milk, *Annett*, 2636-39.  
Increased use would render milk unsaleable, *Boyce*, 2774.  
May alone be permitted in milk; only a small quantity is used; large dose would make milk smell unpleasantly, *Brierley*, 3182.  
Added regularly, in summer only, by one dealer, *Brierley*, 3188.  
Preferred to boracic acid, *Brierley*, 3215.  
Never found in butter, *Hehner*, 5610.  
Milk vendors use formalin and borax-boracic acid equally, *Richmond*, 5650.  
Small quantity only required to preserve milk, *Hutchison*, 6742.  
In 2000 would not flavour milk, *Halliburton*, 7586-90.  
More in imported French than in English milk, *Brierley*, 3236-43, 3268-73.  
Should not be used in milk, *Bannister*, 3660.  
Found in milk, skim milk and separated milk, *Cassal*, 3816.  
Objects to 20000 in milk, *Cassal*, 3875.  
Does not think milk with 10000 would be undrinkable by reason of taste, *Cassal*, 3875-77, and footnote.  
For ordinary individual taking a pint of milk daily, 20000 safe, *Foulerton*, 4048-49.  
Formic aldehyde, a powerful poison in undiluted form, but not poisonous as used in milk, *Foulerton*, 4139-40.  
In 10000 would lead to consumption of liquid, fatal to fish in five hours, *Foulerton*, 4141.  
Altogether objected to in milk; if allowed quantity should be very minute, *Stevenson*, 4829-31.  
Getting more used, *Tubb-Thomas*, 4975-76.  
Used in milk less frequently than boracic acid, *W. C. Williams*, 5160.  
Enables stale milk to be sold as fresh, and puts a premium on cleanliness, *Williams*, 5218.  
Largely used in summer but not in winter, *Kaye*, 5444-46.

## 68c 5. MILK :

Formic aldehyde should be prohibited in milk. Purchaser may be prejudiced by formaldehysed milk, *De Hailes*, 3966-67.

## 68d 1. PRESERVATIVES :

Have largely superseded salt, *Lovell*, 714.  
Not deemed necessary by Aylesbury Dairy Company, *Boseley*, 1018-21.  
Prejudice against food so treated had by some people, *Copeman*, 1204-5.  
Permit of unsaleable goods being sold, *Voelcker*, 1714-15.  
Should be scheduled after inquiry, *Foulerton*, 4167.  
A changing quantity, *Foulerton*, 4168-69.  
Studied in food, *Stevenson*, 4797; *W. C. Williams*, 5147.  
To be avoided as not food, *Corfield*, 5123.  
Studied in milk and butter recently and specially as regards West Riding, with a population of over one million persons, and investigation to be continued, *Kaye*, 5437-42, 5496.  
Studied extensively, in food, *Hehner*, 5564.

68. PRESERVATIVES, USE OF—*continued*.

## 68d2. PRESERVATIVES: Use, General:

Apart from salt objectionable, and foreign to the body, *McFadyean*, 1756, 1778-81.

Time not a factor, *McFadyean*, 1783-87.

Discarded in some instances by vendors as a result of examination made for "Tancet," *Vasey*, 1978-85.

Increasing, *Vasey*, 1995.

Boric acid most frequently used; then salicylic acid, formaldehyde, and in a few instances benzoic acid, *Vasey*, 2037-40, 2043.

Dates of first known use, *Vasey*, 2079-85 (App. No. 10).

Increasing, but not much known to medical men; hence results of use not generally known or traced, *Handford*, 2277, 2296-99.

Formaldehyde and boric acid found, *Boyce*, 2711.

Found only in milk, wine, and beer; and only formalin and boric acid found, save as regards wine, in which was salicylic acid, *Brierley*, 3169-70, 3191.

Increasing, especially of late, *Brierley*, 3173, 3207-9.

Not much in use prior to 1875, *Brierley*, 3274-77.

Statement prepared and handed in, *Lowe*, 3296-97 (App. No. 16).

Studied, *Robinson*, 3300.

May be taken in many foods in a day, *Robinson*, 3336.

Boric acid, borax, salicylic acid, and formaldehyde in common use, the latter a stronger antiseptic than the first, *Blyth*, 3439, 3463.

Widespread for keeping foods saleable, and for palming off stale, inferior, and even bad articles, *Cassal*, 3802.

Used for foods other than milk, but not so necessary, *Foulerton*, 4068-69.

Boric compounds, formalin, and salicylic acid most commonly used, *W. C. Williams*, 5148.

Increasingly in use, *Kaye*, 5444.

List of five handed in with data as to use, *Kaye*, 5455 (App. No. 30).

Recklessly used, *Kaye*, 5462.

Fairly generally used throughout the country; but less among co-operative societies doing a quick trade, *Kaye*, 5473. Use of preservatives known as general during past seven years, 5482. Present knowledge of extent of use not very great, 5435, but hope held of further information resulting from prolonged inquiry, especially as to seasonal use, 5496-97.

Preservatives are of use in the interests of public health, *Hutchison*, 6719, 6768.

Becoming more common in every-day articles of food, *Hope*, 6840. Same objection does not lie as with milk and cream, 6841.

Heard of as being most in use are formalin, salicylic acid, boric acid, and borax, *Stirling*, 6933-37.

## 68e1. BACON: Preservative:

Washed off on arrival, *Hudson*, 506-8.

Little used in English bacon and ham, *Hudson*, 505.

## 68e2. BACON, American:

Used, *Hudson*, 505.

Tend to increase trade, *Hudson*, 517-18.

Borax dusted over pork coming in large and increasing quantity from America: procedure not deemed objectionable, *Hope*, 6878.

## 68f. BEER:

Ten grains of salicylic acid per quart harmless, *Bond*, 3118.

Most often by sulphurous acid, in small quantity; acid also used for cleaning brewery vessels, *Bannister*, 3661-62, 3668-70.

Salicylic acid not used in this country; one case of lager beer salicylised, *Bannister*, 3663-64, 3666, 3671.

Bottled beer needs no preservative, *Bannister*, 3666-67.

68. PRESERVATIVES, USE OF—*continued*.68f. BEER—*continued*.

Beer as preservative subject of evidence before Beer Materials Committee of 1898, *Schidrowitz*, 7218-22 (App. No. 34). Use of salicylic acid decreasing and of sulphites increasing, 7247-49.

## 68g1. BUTTER:

Not known, *Kellitt*, 50.

Originally in butter collected from farmers in small quantities, *Hefner*, 5595.

Unsalted, 1 lb. to 112 lbs. of saltless butter, *Sandes*, 79.

Has revolutionised Irish butter trade, *Sandes*, 88.

Have almost entirely replaced salt, *Sandes*, 80; *Dale*, 243.

Generally insoluble and unworkable, *Shanahan*, 346-47.

Dry form now in use, *Shanahan*, 350.

Complaints obviated, *Hudson*, 551-52.

Not used by Hudson Brothers, *Hudson*, 492, 546.

Have conduced to growth of trade, *Lovell*, 709, 711.

In nearly all butter, *Lovell*, 716.

Not needed in well-made butter, *Riley*, 819, 836-37.

None used by Aylesbury Dairy Company, *Boseley*, 975, 977-81, 1017, 1036-37; nor at Dunragit, *McCracken*, 2854.

In from 50 to 60 per cent. of amount sold in London; and in all French produce, *Boseley*, 957, 973-74, 976, 1013-16.

Distinct from that in milk and cream, *Voelcker*, 1692, 1748.

Only salt necessary, *McFadyean*, 1756, 1758.

Would not inhibit volatile agents, *McFadyean*, 1757.

Physiologically indefensible, *McFadyean*, 1758.

Not needed in butter carefully made and quickly consumed, *McCracken*, 2946.

Necessary, *De Hailes*, 4003, 4016-19.

None used by witness, *Carrington Smith*, 4454-56, 4473.

Butter not in same case as milk, *qui* use of preservatives, *Tubb-Thomas*, 4950-51. A difficulty arises in supplying large towns with fresh butter, 4952, at certain seasons, 4953, but Danish butter largely imported, 4954-55, without difficulty. Australian butters are preservative, 4956. Many home creameries use preservatives, 4957. None known which do not, 4958. Witness would modify his view if he knew that large creameries did not use them, 4959-60.

Butter not on same footing as milk *qui* preservatives, *Carrington Smith*, 4558-60; *Corfield*, 5136-37.

Butter churned by Aylesbury Dairy Company contains no preservative, *Hattersley*, 5796-97. Imported French butter contains a preservative, 5797. It is a factory butter, 5798-99. Preservatives seem necessary to Normandy saltless butter, 5800-1, 5835, system at fault, 5836.

Preservatives should not be requisite for butter from field-drawn milk, *Lough*, 6629.

## 68g2. BUTTER: Admixture:

Very intimate, *Sandes*, 95, 96.

Exclusive use of Normandy system not known of, *Dale*, 268.

Before salt, after expression of butter-milk, *Shanahan*, 352-56.

By whom, unknown, save as by dairy-farmer in one instance, *Williams*, 2115.

## 68g3. BUTTER, Australasian:

Australian butter not preservative, *Hill*, 2475-77.

Up to 1899 Australian butters found to be invariably preservative, *Richmond*, 5692-93; when two good saleable butters were found free, 5694-96, 5736-37, 5740, but with salt, 5738, some 2 or 3 per cent., 5739, and no absolute necessity for preservatives inferred therefrom, 5697. Quantity in such butters reduced of late, 5698, from 1 to  $\frac{1}{2}$  per cent., 5699, without known change of mode of transit 5700-1.

68. PRESERVATIVES, USE OF—*continued*.68g 3. BUTTER, Australasian—*continued*.

Preservatives added to New Zealand butter to aid keeping after defrosting, *Cameron*, 6171; but not universal, 6172, on account of recent action over here. Finest butter is preserved slightly, 6173. Preservative very exactly blended with butter, 6184. Not likely to be added to milk by farmers because unnecessary, 6186-96. Preservatives facilitate New Zealand butter trade, 6203, essential to keeping the butter in the finest condition, 6204, but the trade not absolutely dependent on their use, 6205, though without them quality and price would decline, 6206. One-half per cent. of preservatives for butter quite enough, 6234-40, and satisfaction would be felt at any limit laid down, 6241-42. New Zealand Government have legislated as to preservatives, reserving the right to prohibit them if need be, 6246.

Experiments made by New Zealand Government to determine results of adding preservatives to butter, *Cameron*, 6174; and  $\frac{1}{2}$  per cent. of preservative found beneficial for keeping butter, 3 per cent. of salt being also added, 6175-81, 6274, and preservative being boracic acid and borax, 6182, for ease of application, 6183, in powdered form, 6184. Evidence in a report of Mr. Sorensen when Chief Commissioner of New Zealand, Department of Agriculture, against use of preservatives in butter, 6252-69. Only one churning used for the experiment, 6270-73. Further experiments have been made, 6275-78, 6308-9. Conditions of uncleanness obtain still in New Zealand dairy farms, but these not held to vitiate the results of the above experiment, 6279-89.

Preservatives first used experimentally in a few tons of New Zealand butter, *Sorensen*, 6995, commercially nothing was gained by using them, 6996, but one or two boxes were reported to be very fine, 6997-98. Use given up, as expensive, 6999, and London agents quite satisfied, 7001. Opinion was divided in New Zealand a few years back as to preservatives, 7001. Of circularised factories, 60 per cent. deemed them to be unnecessary or useless, and only 20 per cent. were in favour of their moderate use, 7002. Some of latter, largest exporters in the colony, 7003, and advocated only  $\frac{1}{4}$  per cent., 7004;  $\frac{1}{2}$  to  $\frac{1}{2}$  at the very outside, 7005. At the time witness left the colony,  $\frac{1}{3}$  of butter reaching England was not preserved, 7006-7. Present condition of affairs not known, 7008, 7129, but reason to think increase of use since leaving, 7009. No doubt some pressure has been exerted, 7010-12.

Experiments made with preservatives, as chief dairy expert for New Zealand Government, *Sorensen*, 7013, shewing slightly greater keeping power of chemically treated butter, 7014, the flavour being better preserved, 7015,  $\frac{1}{2}$  per cent. being the amount admixed, larger quantity flavouring the butter, 7016, giving it a saline taste, 7017. Experiments left witness unconvinced as to desirability of preservatives, 7018-21.

68g 4. BUTTER : Brittany :  
Requisite unless used rapidly, *Trengrouse*, 634.

68g 5. BUTTER : Canadian :  
Sent without preservatives, *Riley*, 819, 839.  
Boracic acid advised but not universally used, *Clement*, 1506-7, 1552-53.

68g 6. BUTTER : Character :  
Never analysed, *Sandes*, 83. Only one kind used, 100-101. Boracic acid, 102.

68g 7. BUTTER : Colonial :  
Average quantity  $\frac{1}{2}$  per cent., *Clement*, 1536.

68g 8. BUTTER : Complaints :  
Unknown, *Sandes*, 87.  
None known of, *Dale*, 255.

68. PRESERVATIVES, USE OF—*continued*.

68g 9. BUTTER : Consumption :  
Used for years, *Hudson*, 500.

68g 10. BUTTER : Danish :  
Not aware of, *Kellitt*, 45, 49.  
Used, or butter would not keep, *Sandes*, 117-19, *Lovell*, 717, 771.  
Winked at, *Sandes*, 117-19.  
Not advocated by Danish instructors, *Sandes*, 120.  
Prohibited, *Dale*, 247, *Shanahan*, 357-59.  
In England not known, *Dale*, 316-17.  
Prohibition has not affected trade, *Shanahan*, 357-59.  
Believed not to contain any, *Trengrouse*, 630, 654, *Bosley*, 1031, 1034-35.  
Obviated by short voyage, *Trengrouse*, 682.  
Only salt used, *Trengrouse*, 686-87.  
Not requisite, *Trengrouse*, 688.  
Not always used, *Lovell*, 718.  
One-half per cent. wherever possible, *Lovell*, 752-53.  
Claims not to use, *Clement*, 1514.  
Accepted as containing none, *Davidson*, 1594.  
Believed to be used, *Davidson*, 1595-96.  
Butter unpreserved, *Bannister*, 3535.  
Butter unpreserved now as a matter of protection against Irish competition. Boracised until recently, *De Hailes*, 3986-99.  
Preservatives not used in Danish butter, that is, in one-half of total foreign butter trade of England, *Faber*, 4317.  
Butter in Denmark preserved to a small extent only, prior to prohibition of preservatives, *Faber*, 4219-20, and then only by boron base preservative, 4263-65. Most butter is salted to some extent, 4221. Some sent not salted, some  $\frac{1}{4}$  per cent., but most about 1 per cent., 4222. Pasteurised butter adjudged the best, 4309-11.  
Free from preservatives, and practically also from salt, *Hehner*, 5600-1.

68g 11. BUTTER : Detection :  
One per cent. detectable, *Hudson*, 497-98, 500.

68g 12. BUTTER : Irish :  
Not always used, *Dale*, 274.  
Not needed if consumption were rapid, *Trengrouse*, 690-91.  
Enable butter made on old methods to be successfully marketed, *Lovell*, 747.  
Extensively used, *Riley*, 820.  
Seldom used in butter sent to Cork, *Dunn*, 3013, 3014.  
Used in factory butter, *Dunn*, 3013, 3015.  
Generally soluble borate of soda, *Dunn*, 3013, 3051.  
Quantity advised to traders is 1 lb. per 112 lbs. of butter, *Dunn*, 3014.  
Nothing in quality to necessitate, *Dunn*, 3023.  
Frequently mixed with salt first, 1 lb. to 100 lbs. of butter, *Dunn*, 3051-53.  
Irish fresh butter trade depends entirely on preservatives, *Gibson*, 6312-13, and these necessary for Irish salt butter also, 6314. All butter controlled by witness is preserved, 6328, 6373. Trade will require preservatives until defects in present system are righted and butter is no longer required to keep as now, 6361, 6385, 6390-92, 6395-96. No complaints of preserved butter, 6374-75, but complaints of unpreserved butter, 6376.  
Preservative in Irish saltless butter, 1 lb. to 112 lbs., *Gibson*, 6328, 6377, analysing out to 0.8 per cent., and quite sufficient, 6329, 6378, 6400; 3 lbs. of salt added makes a salt butter, 6330. Use of preservatives in butter a question of rapidity of consumption, 6350. Consignees of witness know of preservative in butter, and private clients demand it, 6351. Borax and boracic acid the base of all the preservatives used, 6357. Preservatives will remain requisite till present defects of manufacture and the necessity for storage are removed, 6394-99. Conditions of housing of cattle in Ireland more favourable to prohibition of preservatives than in Denmark, *Lough*, 6656-58.

63. PRESERVATIVES, USE OF—*continued*.

## 68g 13. BUTTER : French :

In all, *Roseley*, 957, 973-74, 976, 1013-16.

## 68g 14. BUTTER : Normandy :

On soaked wrappers, *Dale*, 266.

Wrappers and added preservatives, *Dale*, 267.

One-half per cent. used, *Lovell*, 762-63.

Salt or preservative used, *Bannister*, 3544-45.

## 68h. CIDER.

American, of low alcoholic strength, and bad keeping quality, contains salicylic acid ; some also glycerine, *Voelcker*, 1655-58.

Ten grains of salicylic acid per bottle harmless, *Bond*, 3117.

Salicylic acid may be used ; it requires a preservative, *Bannister*, 3665.

Cider and perry need no preservative ; none used by witness, but sulphur burned in vessels, *Radcliffe-Cooke*, 6576, 6604 ; and vessels kept clean, 6605-6 ; and skim milk used for thickening purposes, 6576. Sulphur fumigation destroys germs and slightly retards fermentation, 6577, 6609-10. Many makers use preservatives, 6578 ; nearly all being preparations of borax or salicylic acid, 6579 ; which are put in at any stage of manufacture to stop fermentation ; sugar of boron being one kind, used also in mineral waters and non-alcoholic beverages, 6580. Sugar of boron used also in brewing. "Cynin" also used in cider ; it consists of a solution of salicylic acid and borax in glycerine ; experiment showed it an excellent preservative, 6581 ; but the cider kept by its use was not matured, and the control unpreservatised cider had been lying about unheeded. Another cider preservative, "Walter Gregory's powder," consists of salicylic acid and a small quantity of red oxide of iron, 6582. Formalin seldom used in cider. "K.M.S." not analysed. Antiferments are used to make bad cider good. "Hawkes' Anti-ferment" of a different class. Formalin used for brewing and mineral waters. "Hawkes' Cider Restorer" used for decomposed, ropy and unhealthy cider, 6585. Cider not often fortified, 6587-88. Preservative advertisements known of are from Somerset and Devon, 6589 ; handed in, 6603. Nothing known of the use of preservatives in French cider, 6591-92. Preservatives are substitutes for cleanliness, and induce carelessness, 6593. Public probably know of their use, 6594. Certain firms advertise no chemicals as used, 6595, 6599-6601, and then use them, 6596-97. Declaration of preservatives should be made by label on the bottles or vessels, 6598-99. No objection to sulphur sterilisation of vessels, 6606. Would not use boracic acid or formalin, 6607 ; they stop fermentation, cider never reaches maturity, and they are harmful, 6608. If preservatives permitted no reason why present non-users should use them, 6611-12 ; and prohibition would affect only the dishonest trader, 6613.

Preservatives in cider used by best makers in small quantity, *Symons*, 7264-65. Salicylic acid, saccharin, sulphite of lime or soda used, 7266 ; the saccharin being soluble, 7267 ; a product of coal tar, 7268-69 ; identical with "Tigress Brand" of saccharin, 7270-72. Preservatives good in small quantity to arrest viscous fermentation, 7273-77. Has used preservatives hitherto under certain conditions, 7278-80. They should not be prohibited but limited, 7281 ; as to quantity, 7282-84. Salicylic acid not always used, and only a small quantity at any time ; a standard should be fixed, 7285 ; not more than  $\frac{1}{2}$  to 1 oz. of salicylic acid per 116 gallons, 7286-87 ; and  $\frac{1}{2}$  to  $\frac{1}{4}$  oz. of saccharin 7288. Beer showing incipient taint would be beyond the aid of saccharin, 7289 ; as also would cider. Preservatives should be used from one to three months before public get the cider. Salicylic acid held in Court to do more good than harm as used in cider, 7290. Only best makers should be allowed

63. PRESERVATIVES, USE OF—*continued*.68h. CIDER—*continued*.

to use it, 7291-92. Too much preservative might be harmful, 7305. From 1 to 2 oz. of soda would be used per pipe, 7306. About  $\frac{1}{2}$  more used in America, 7307-9, and in Germany saccharin and salicylic acid used largely, 7310, about  $\frac{1}{2}$  more than above suggested standards, 7311. Has never used as much as Germans or Americans, 7312. A witness holding that preservatives are not needed in cider, not one having a great experience, 7293. Pure cultures can be obtained for beer manufacture, 7294-99. Has isolated pure yeast from apple pulp, 7300, and has identified the organisms concerned in cider manufacture, 7301. There are many kinds of germs, yielding differing results. A constant germ might obviate need for preservatives in cider, 7302-4. Cleanliness no substitute for preservatives, 7313. Difficult to exclude such bacilli in cider-making as to obviate use of preservatives, with a weak percentage of spirit, 7314-17. Sick cider would not be salicylised, 7318, but with indications of going wrong the acid would be added as a preservative, 7319-23. Such indications are exceptional, 7326. Pasteurising does not work well, 7324. It causes insipidity. It is practised in France and Germany, 7325. Too late to pasteurise cider quite ready for consumption. Preservatives in cider not universally advocated, but honest traders should be permitted to use a small quantity in case of necessity, 7327, 7335. Cider industry very ancient, 7328, but progressive, 7329-30. Perfection of keeping cider probably attained, 7331, and knowledge has followed experience, 7332, by the aid of bacteriology, 7333, 7335. Difficult to say if manufacture of cider has improved, 7334.

## 68j 1. CREAM :

Not known to be used, *Dale*, 338.

Necessary to keep cream a day in summer, *Hudson*, 515.

In jugs issued by Aylesbury Dairy Co. used to be preservatised ; practice stopped, *Boseley*, 981, 1017, 1036, *Richmond*, 5667-72, *Hattersley*, 5789, 5791.

None used in Aylesbury Dairy Co.'s clotted cream, *Boseley*, 982-83.

Needed if clotted cream is to keep more than two days in summer, *Boseley*, 984.

Needed for small vendors but not by large companies, *Boseley*, 1039.

Powdered borax applied, and not always intimately mixed, thus tending to vitiate analyses, *Walford*, 1901-6.

Boracic acid largely used, *Handford*, 2278-80.

Boracic acid and salicylic acid found, *Hill*, 2362-64, 2385 ; from 24 to 42 grains of boracic acid per lb., *Hill*, 2367.

If found at top of jars substance not properly treated, *Bell*, 2829.

Not needed in, *Bell*, 2830, 2837, 2839 ; *Cassal*, 3804, 3819.

Admixed in a little milk, and well stirred in, *McCracken*, 2864, 2868.

All preservatised at Dunragit, *McCracken*, 2853, 2865-67.

Would not keep well without them, *McCracken*, 2869.

Boracic acid found from 0.104 to 0.291 per cent. of boron-trioxide, *Cassal*, 3813.

Medical men hold preservatives in cream to be dangerous, *Cassal*, 3820.

Trade would cease if preservatives were prohibited, *De Hailes*, 3984, 4033.

All London potted cream preservatised, *De Hailes*, 3985.

Cream samples found to contain boracic acid as a borate, 17 to 38 grains per pint *W. C. Williams*, 5164-65, both potted and bottled, 5166. One sample unfit for use, 5167-68, and deemed to be injurious to health, 5325. Potted samples from grocers, 5221, who require the preservative to keep the cream, 5122-26, more than the dairyman, 5127-31.

68. PRESERVATIVES, USE OF—*continued*.68j 1. CREAM—*continued*.

Nearly always boric compounds, *Hehner*, 5584.

Cream as sold by milkmen rarely preserved, *Hehner*, 5576, 5581. Cream from grocers almost always preserved, 5582-83, always boric compounds, in many cases 56 grains per lb., 5584. Grocers' trade in cream calls for preservatives, 5585-88, and induces them to use them, 5589-91, and mislead the public as to keeping quality of cream, 5592.

Cream preserved by formalin, borax, boracic acid, and saccharated lime (called "viscogen") which retards curdling and evidence of sourness and is an alkali, *Richmond*, 5659-64, "Special Cream Compound" used, a borax-boracic acid-saccharin mixture, 5664-66. Aylesbury Dairy Co. used to use 0.2 per cent. of boracic acid in cream, 5667, not now, 5668, it was objected to and found to be unnecessary, 5669. No preservative used now at all, 5670-72.

Cream collected by Aylesbury Dairy Co. in London except one supply from Sussex, *Hattersley*, 5787-88. No preservative used, 5789, even in clotted cream, 5791, also made in London, 5792. Only one verbal and one letter of complaint of cream per 2,000 and 20,000 quarts respectively, 5790, and less frequent relatively than as to milk, 5872-78. No preservative required for Devonshire clotted cream sent to London, 5793. Clotted cream keeps longer than ordinary cream, 5794-95. Grocers sell cream because they can preserve it, 5854-56.

Cream has been sold without any preservative, *Lough*, 6688-89.

Cream not much used in children's hospitals, *Still*, 6803. Used chiefly for marasmus, 6804. Same objections apply as to preservatives as in the case of milk, 6805.

Cream more commonly preserved than milk, *Hope*, 6834, and sold both by dairymen and grocers, 6836. Preservatives not necessary, 6835, and not approved by medical authorities, 6837.

Cream needs no preservatives if traded by proper channels, *Sorensen*, 7116-17, daily, 7119-20. The grocery trade has made them requisite, 7118. None used in Copenhagen, 7120, with extremes of temperature, 7121-22, and cream travelling three to five hours, 7123-24. From 140 to 150 grains of boracic acid found per gallon of cream taken haphazard in Manchester, 7141-45.

## 68j 2. CREAM : Admixture :

Often all at top of jar, *Voelcker*, 1642.

## 68k. CREAMERIES :

Long used at Dunragit, *McCracken*, 2852.

Butter demands a preservative, *Bannister*, 3536-37; without preservative it goes off quickly; much used, 3538-39; not necessary in butter for quick consumption, 3540; necessity not universal, even in creamery butter, 3541-43.

Nearly all the Irish creameries use preservatives in summer, 6621. Only butter made *Lough*, 6622. Preservatives not essential to creamery industry. They are asked for, but less quantity than used would suffice. No complaints made of use of preservatives, 6625. Use of preservatives deprecated in agricultural products, 6659. They would be quite unnecessary in a few years in creameries with proper organisation, 6660. Presumably preservatives in butter would be harmful, 6668. They should be done away with, and are being got rid of in witness's creameries, 6676. Borax chiefly used, 6681.

## 68l. DAIRY PRODUCTS :

Milk, cream, butter, and condensed milk most frequently treated with borax, boracic acid, and formalin; very occasionally with salicylic acid, nitrates, and sulphites, *Boseley*, 951-52.

Not needed, *Long*, 4571, 4577-78.

68. PRESERVATIVES, USE OF—*continued*.68l. DAIRY PRODUCTS—*continued*.

Used promiscuously, 56 grains per gallon known, and 1-20th oz. per gallon, *Long*, 4579-81.

Use opposed by the Central Chamber of Agriculture, by formal resolution, *Curvington Smith*, 4410-11, 4487. Preservatives advertised at Islington dairy show, 4540-44. List of preservatives handed in, 4544-47, (App. No. 11). Preservatives held to be seldom used by farmers, but often by dealers, 4549.

Unnecessary and undesirable, and a cloak for dirt, *Kaye*, 5448-51, 5519-20.

Not used by Aylesbury Dairy Company, save in some imported butter sold by them, *Richmond*, 5641-42.

Commonly used, *Fisher*, 4717.

## 68m. FRUITS, BOTTLED :

Not used by Messrs. Keiller, *Boseley*, 1062.

## 68n. GROCERY TRADE :

Salt, saltpetre, sugar, oil, vinegar, and glucose mostly used, *Copeman*, 1169-70.

## 68o. HAMS :

Dusting by, and packing in, alone known, *Kellitt*, 26.

One lb. needed per cwt., *Gregson*, 924.

None detected on Danish hams, *Kellitt* 69-72.

## 68p. JAMS :

In some 50 per cent. of makes, *Boseley*, 968.

None in fruit for jam, *Boseley*, 969-70.

None by Messrs. Keiller, *Boseley*, 1143.

Messrs. Keiller would like to use them, *Boseley*, 1144. Needed for large quantities of jam, as made, if required to be kept several months, unless it be cooked to stiffness, *Boseley*, 1084-85.

Sugar used, *Copeman*, 1231.

Preservatives not known to be used in preserved fruits and jams; not used by Crosse and Blackwell, *Blackwell*, 4863-64, 4871, 4875, and quite unnecessary, 4865, 4872, 4918-19. None used in jam pulp, 4866-67. Jam from imported pulp only as regards apricot made by Crosse and Blackwell, 4905-7, and believed to be free from preservative, 4908-9, which would flavour the pulp, 4910-13. No preservative needed in any pulp, 4914-17. Preservatives do not cheapen jam, 4920-22.

Jam found to contain salicylic acid from  $\frac{1}{4}$  to  $4\frac{1}{2}$  grains per lb., *W. C. Williams*, 5180. Bottled fruits and some jams found free from preservatives, which seem not to be needed in large, clean fruits, 5181, as opposed to small and easily damaged fruit, 5182. No proceedings taken, 5183. Difficulty apart from preservatives thought of as to small fruit jams, 5184, but not upheld if makers do really get on without them:  $4\frac{1}{2}$  grains per lb. in any case too much, 5185. Use not decreasing, 5264-67. Quality of fruit a prime factor, *quid* preservatives, 5268-71. With proper care all round salicylic acid not requisite, 5272, and used, where used, often without thought, 5273, and its prohibition would not injure legitimate trade, 5274. One unpreserved sample of jam contained mould spores, 5326-30. Imported pulps seldom preserved; preservative unnecessary, 5331-35.

## 68q. MARGARINE :

Borax and boracic acid used, *Lovell*, 806; sometimes in summer only, *Clement*, 1522-25.

In Birmingham 84 per cent. of samples contained boracic acid, *Hill*, 2349-50, 2385, 2388.

Used at Dunragit, *McCracken*, 2853. Necessary in trade of to-day, *McCracken*, 2857. Dutch method of milkless and unpreserved manufacture not known, *McCracken* 2891-93. Quantity needed about  $\frac{1}{2}$  per cent., *McCracken*, 2929-30.

PRESERVATIVES, USE OF—*continued*.68q. MARGARINE—*continued*.

Margarine samples nearly all contained borax or boracic acid, *W. C. Williams*, 5172, 5251-54. Mostly sold as butter, 5173-74, and much used in cooking; usually some 20 grains per lb., 5175. Service of boracic acid or its necessity doubted, 5255-61, 5263, but trade seem to regard it as necessary, 5262.

No necessity, *Hehner*, 5599, 5603-4.

## 68r. MEAT FOOD:

In Birmingham in 64 per cent. of samples examined boracic acid from 10 to 45 grains per lb. found, *Hill*, 2352-53, 2385, 2410-14; acid generally intimately distributed, 2357-60; taste would reveal its presence, 2361.

In imported American meat, *Boyce*, 2743.

Found in meat and tripe, *Kaye*, 5444.

Cow carcasses known to be dredged all over, *Kaye*, 5462.

## 68s 1. MILK:

Perhaps in 50 per cent. of London milk supplies, *Boseley*, 956.

None by Aylesbury Dairy Company, *Boseley*, 1017, 1019.

Boracic acid most general, *Voelcker*, 1639, 1643. Salicylic acid formerly used; not now found, *Voelcker*, 1643. Boracic acid and formalin most commonly used, *Stevenson*, 4804.

Formalin and boron base preservatives mostly used, *De Hailes*, 3930-31.

Formalin never yet found, *Voelcker*, 1643.

A serious question, *Walford*, 1927.

Should be allowed guardedly in summer, *Vasey*, 2047-51.

In 9 per cent. of samples examined in Birmingham, from 1896 to 1899, boracic acid and formaldehyde being in question, *Hill*, 2332, 2385, 2461-63.

In 2 per cent. of samples from farmers, *Hill*, 2341.

Most frequent in summer, *Hill*, 2343, 2389-93.

Same sample contained boracic acid and formic aldehyde, *Hill*, 2381-82.

Old milks naturally would be preservatised, *Hill*, 2401-8.

Lower classes most likely to get such milk, *Hill*, 2450.

Disapproved of by Society of Medical Officers of Health, *Hill*, 2522.

Should be effected soon after milk drawn, *Annett*, 2681.

At time of milking, *Rideal*, 3697; *Foulerton*, 4050-57.

No known difficulty in way of adding at time of milking. It is done by some, and might be done by all, *Rideal*, 3700.

Habitual by some farmers and dealers in Hants in summer, *Brierley*, 3188, 3236-38.

Often present though not found, *Robinson*, 3307.

Dover milk largely free from, and Broadstairs milk said to be preservatised, *Robinson*, 3308-9.

Not approved, *Blyth*, 3447.

May be partial, and still indiscriminate, *Bannister*, 3631-33.

Should not be permitted for relief of small vendor, an undesirable milk seller, *Cassal*, 3805.

Substances chiefly used are drugs, boracic acid, borax mixtures, or solutions, salicylic acid, formaldehyde; in some cases benzoic acid, probably as benzoate of soda, and borofluoride. All are foreign ingredients, and are liable to be added in needless quantity, *Cassal*, 3812.

Distance a factor, *De Hailes*, 3926-27, 3948-49, 4004-9.

Largely used in London, and present trade demands preservative, *De Hailes*, 3923-25, 3928-29.

Lesser of two evils, *De Hailes*, 4031.

Should not be preservatised, *W. C. Williams*, 5220.

Largely used in summer, but not in winter, *Kaye*, 5444-46.

68. PRESERVATIVES, USE OF—*continued*.68s 1. MILK—*continued*.

Samples largely free, though both formalin and borates found, as regards country milk, *Hehner*, 5576-79.

Better than sour milk, *Hutchison*, 6720-21, or bad food, 6749-50, especially milk, 6751-52.

## 68s 2. MILK: Admixture:

Quantity may vary in different samples, *Voelcker*, 1640-41, 1671.

May be repeatedly added, haphazard, *Voelcker*, 1672-75.

By whom unknown, save as by dairy-farmer in one instance, *Williams*, 2115.

No precise method, *Williams*, 2119.

May be repeated, *Williams*, 2120.

Preservative added to a little milk, then intimately mixed with bulk, *McCracken*, 2862-63.

Not used by farmers supplying Dunragit creameries, *McCracken*, 2877-79, 2925-27.

Systematic, at Dunragit creameries, as each can is ready to go out, *McCracken*, 2937.

Repeated oft-times, *Brierley*, 3183-87.

Should not be left to consumer, *Rideal*, 3777.

Should be used immediately after milking, *Annett*, 2681; *Foulerton*, 4050-57; at time

of milking, *Rideal*, 3697-3700.

Nothing to prevent consumers adding preservatives to milk, but practice not known, and to be deprecated, *Foulerton*, 4174-81.

Repeatedly made, though this denied, *Long*, 4604-12.

## 68s 3. MILK: Adulteration:

Common in preservatised milk, *Voelcker*, 1652.

## 68s 4. MILK: Complaints:

None made to Dunragit Creameries, *McCracken*, 2880.

## 68s 5. MILK: Condensed:

Australian sample contained half per cent. of boracic acid, *Voelcker*, 1645-51, 1677-81.

Not requisite, *Voelcker*, 1651.

Found to contain boric compounds, *Cameron*, 2528.

## 68s 6. MILK: Creamery Milk:

None used prior to reaching creamery, *Sanders*, 124.

## 68s 7. MILK: Dangerous:

Unnecessarily so, *Jones*, 1309, 1362, 1365.

Milk of bad-keeping quality enabled to be sold as good milk, *Voelcker*, 1715.

Might be distinctly so, if amount useful *Fadyean*, 1752.

## 68s 8. MILK: Objectionable:

On ground of injury to health, but no case of injury known as regards preservatised dairy

produce, *Carrington Smith*, 4553, 4561-64.

Not known to witness that preservatised milk cannot be used for butter-scotch, *W. C. Williams*, 5243-45, 5248-50.

## 68t. PERRY:

Needs no preservative, *Radcliffe-Cooke*, 6576, 6604.

## 68v. PORT:

Boric compound found, *Cameron*, 2528.

## 68w. SHERRY:

One sample salicylised, *Hill*, 2364; *Brierley*, 3191-96.

## 68x. TEMPERANCE DRINKS:

Not by Crosse and Blackwell in lemon squash or lime juice, *Blackwell*, 4884-85. They would be convenient in the latter to prevent moulding, 4886, and are no doubt largely used, 4887-88.

Temperance drinks found to contain much salicylic acid, *W. C. Williams*, 5186.

Lime juice cordial found to contain from 20 to 108 grains per gallon; none is needed, 5187. The acid stops fermentation, 5188.

Salicylic acid and formalin, and salicylic acid and boracic acid found in samples, 5189.

Unsweetened lime juice, but no sweetened lime juice cordial found unpre-

68. PRESERVATIVES, USE OF—*continued*.68x. TEMPERANCE DRINKS—*continued*.

servatised. In lemon squash 50, in ginger wine 118, in raspberry wine 133, in orange wine 103, and in black currant wine 140 grains of salicylic acid per gallon, 5190-92, and the acid found in herbal ale, 5277, all really non-alcoholic wines, 5193, 5285-88. Proceedings failed in cases where taken in Liverpool, 5193, because of medical evidence in favour of use of the preservative, 5194-95, and of evidence of manufacturers as to fruit used, but amounts recorded are above all requirements, 5195. Children principal consumers of above beverages, 5278-80, who might thus get large quantities of salicylic acid, 5281-84, 5308-11.

## 68y. VINEGAR:

Boracic acid found in Birmingham, *Hill*, 2362-64, 2385. In malt vinegar 14 grains of boracic acid found per gallon, 2367.

## 68z 1. SALICYLIC ACID: Beverages:

Excluded by reason of hurt to trade by its known inclusion, *Vasey*, 1986.

Found in temperance drinks, to arrest fermentation, *Blyth*, 3460.

May be used in cider, *Bannister*, 3665.

Used in wines, and liquids of weak alcoholic strength, desired to be clear, *Bannister*, 3558.

Proceedings taken for use in lager beer and orange wine, *Bannister*, 3559.

Found in wines, in port wine in varying quantities, up to 3.15 grains per gallon, *Cassal*, 3822. It is a foreign ingredient, 3823-24. In sherry, 1.6 grain per gallon found. Large amounts found in so called British wines, 3824. An amount like 0.7 grain would have little preservative effect on port; would probably be present as the result of blending, 3825. Cheaper wines most preservatised. Has found 26.6 grains per gallon in orange wine, 11.55 grains in British sherry, 4 grains in black currant wine. Prosecution, that failed, in case of orange wine, 3826. Found in beer occasionally; 7 grains per gallon in bottled beer, 4.76 grains in Pilsener beer, 3827. Not many samples of beer examined, 3828. In lime juice 70 grains per gallon found, 3829. Some lime juice found free from it, 3830, and unnecessary hence inferred, 3831.

Found chiefly in lighter kinds of wine, including British wines, with some prosecutions, and in light beers, *Corfield*, 5072.

Found, 150 grains to a gallon of wine, *Hope*, 6923: some 19 grains per pint, 6924. This would, with other such things, upset children, 6925, but is not a serious matter of itself, 6927-28. British wines in question, 6926.

British wine found to contain 150 grains, *Hope*, 6842, 6923.

(See also under Beer.)

SALICYLIC ACID: Food: Use:

Not increasing, *Vasey*, 2042.

Never found in butter, *Hill*, 2351.

Poisoning by use not known, *Hill* 2416-17.

Indiscriminate, not advocated *Bond*, 3112.

Found in a variety of articles, *Cassal*, 3816.

Objection to indiscriminate use, *Stevenson*, 4824-25.

Studied, *Corfield*, 5071.

Common, *Still*, 6808.

## 68z 3. SALICYLIC ACID: Jam:

Chief preservative, *Boseley*, 968; amount,  $\frac{1}{2}$  oz. to one cwt., or  $\frac{1}{3500}$ , *Boseley*, 968; 5 milligrammes to 1 lb. of jam, *Boseley*, 1089-91; boiled with jam, and intimately mixed, *Boseley*, 1087-88, 1092; used, of necessity, in pulps, *Boseley*, 1092; salicylised jam does not go bad, *Boseley*, 1093-95; jam-makers' preservative; a good anti-fermentative, *Boseley*, 986-89.

In strawberry jam,  $3\frac{1}{2}$  grains per lb., *Voelcker*, 1661; presence objectionable, *Voelcker*, 1662-63 1670; covers imperfections, *Voel*

68. PRESERVATIVES, USE OF—*continued*.68z 3. SALICYLIC ACID: Jam—*continued*.

*ker*, 1664, 1706; not necessary in well made jam or fruit pulp, *Voelcker*, 1664, 1704, 1706. Found in Birmingham, *Hill*, 2362-64, 2385. Two grains per lb. harmless, but efficient, *Bond*, 3113-15.

Jam unequally preservatised with salicylic acid; some has none, and some ten times that of others containing the acid, *Hope*, 6843. None necessary, 6844. Manufacturers probably ignorantly reckless, 6845.

## 68z 4. SALICYLIC ACID: Wine:

Ten grains of salicylic acid per pint harmless, *Bond*, 3116.

Preservatives not necessary, and used only since 1875, *Brierley*, 3259-61.

Benzoic acid found, *Cassal*, 3816.

Preservatives, other than brandy, unnecessary in wines imported to this country, *Gilbey*, 4361, 4371, 4380. Salicylic acid heard of years ago in cheap Spanish wine, 4362 Tarragona, 4369; and known in wine producing countries, 4363; really in inferior wines, 4364. It is a preservative, and reduces the amount of spirit required, 4365; arrests fermentation, and is easily detectable, 4366-71. Not known in this country, 4366-67, 4371-75, 4379, 4392, 4404. Light Portuguese wines not likely to be imported, unless fortified or preservatised, 4376; and not known to be imported, 4377-78. "St. Julien," made on banks of Thames, extremely likely to contain salicylic acid, 4381-86. Mineral acids in wine not known, 4405-6.

## 69. PRICE:

## 69a. BACON:

Price of Canadian bacon the inducement to buy it, but English curing of bacon greatly on the increase, *Harris*, 5981-85. American bacon goes mostly to poorer districts, 6018. Price of bacon, if borax prohibited, would only be affected as mode of carriage increased in cost, 6028-33. If America and Canada charged English prices they would sell no bacon, 6034.

## 69b. BUTTER:

If better, dairying would grow, *McFadyean*, 1774.

## 69c. BUTTER: Australasian:

Price of New Zealand butter cheaper than Danish butter, *Cameron*, 6168, and butter coming over unpreservatised sold cheap than preservatised butter, 6207-10.

## 69d. BUTTER: Brittany:

Commands highest price, *Trengrouse*, 698.

## 69e. BUTTER: Danish:

Lessened if kept over a week, *Shanahan*, 379-80.

Relatively high, *Trengrouse*, 697.

Commands good, *Riley*, 843-44; *Hehner*, 5602.

Best, *Clement*, 1513.

Unpreservatised, fetches a higher price than preservatised French butter, *Long*, 4629-42, 4672-76.

## 69f. BUTTER: Irish:

Commands good price, some butter being preservatised, *Gibson*, 6354-55.

Price of Irish winter butter higher than best Danish, *Gibson*, 6326, 6404; some of the former being salted, and some saltless, 6327.

## 69g. MILK:

Would not be raised by prohibition of boracised preservatisation, *McFadyean*, 1773.

If better, dairying would grow, *McFadyean*, 1774.

Of skim-milk, would not allow of sterilisation, *McCracken*, 2908.

Cheapness may mean milk and water, *Brierley*, 3264.

69. PRICE—*continued*.

## 69h. PRESERVATIVES : Butter :

Not affected, *Sandes*, 90-94.

Regulated by use, enabling butter to keep till needed, *Shanahan*, 395-97.

Determines time butter is kept, *Shanahan*, 398.

Does not affect the use of preservatives, *Shanahan*, 405-12.

## 70. PROCEEDINGS :

## 70a. BORACIC ACID :

Cream boracised 16 grains to  $\frac{1}{2}$  lb., or  $\frac{1}{4}$  per cent., *Hudson*, 509-13.

In milk and butter, especially, subject of action by Glamorgan County Council, *Williams*, 2111, 2188, 2190.

May have stopped use of boracic preservatives, *Williams*, 2138, 2144-45, 2221-23.

## 70b. BORACIC ACID : Butter :

Would probably be taken for 1.3 per cent. as at Pontypool, *Jones*, 1311, 1320. Bench held 1.3 per cent. to be injurious to health, *Jones*, 1321.

Taken for 71.4 grains per lb., *Walford*, 1842-45.

Taken successfully in Birmingham, *Hill*, 2367-68.

## 70c. BORACIC ACID : Milk :

Successful in County Glamorgan, *Williams*, 2130-34; and in Birmingham, *Hill*, 2341.

## 70d. BORAX : Butter :

None known on account of excessive weight, *Bennett*, 221-26.

## 70e. BORAX : Ham :

Evidence given *re* boracised ham, *Prossor*, 571-72.

Taken for 56 grains per lb. at Pontypridd, *Williams*, 2226-28, 2234, 2237-38.

## 70f. FORMALIN : Dairy Products :

Successfully taken, *Boyce*, 2709-10.

Successfully taken in Liverpool for formalised milk, *W. C. Williams*, 5158, 5161; and unsuccessfully for salicylised temperance wine, 5158. Use of formalin was increasing, and was checked by the conviction obtained, 5159. Conviction secured because formalin an adulterant and deemed to be injurious to health, 5316-21. Injury not known, 5322-24. No considerable account of case published, 5428-31.

## 70g. PRESERVATIVES :

Difficult on ground of injury to health, *Hill*, 2024-32.

None taken in West Riding by reason of appointment of present Committee, *Kaye*, 5443, 5463.

Have elicited defence that preservatives as used are not a danger to health. Witness disagrees. Another defence has been their use as medicines; but the argument is absurd and the administration of drugs in such manner is most objectionable, *Hope*, 6846.

Ending in convictions, have been taken in a number of instances, *Cassal*, 3795; but necessity of proving injury to health is a difficulty, 3796. Prejudice of customer not now found to be a difficulty as to proof, 3797-99. Expense of procedure is a difficulty with certain local authorities, 3800-1. Certain multiple forms of statement in regard of contained preservative held to be necessary to satisfy the Court, 3817.

## 70h. PRESERVATIVES : Butter :

Taken by Glamorgan County Council when 34 grains per lb., *Williams*, 2129. Convictions have followed proceedings by the Council, *Williams*, 2135-36.

## 70j. PRESERVATIVES : Milk :

Would be taken at Newport (Mon.) when found, save in case of formalin, *Jones*, 1405, 1408-11.

None instituted against Dunragit Creameries, *McCracken*, 2881.

70. PROCEEDINGS—*continued*.

## 70k. PRESERVATIVES : Cider :

Ground for such, if quantity large, *Voelcker*, 1659.

## 70l. PRESERVATIVES : Cream :

Fine inflicted in case when 0.464 per cent. crystallised boracic acid present, *Cas* 3852-54.

## 71. PROHIBITION :

## 71a. BENZOIC ACID :

Needed, *Vasey*, 2046.

## 71b. BORACIC ACID :

Was followed by reduced sale, and growing demand for other preservatives, *Jones*, 1392-94.

Preferred to declaration, *Cameron*, 2579.

In force in Austria, *De Hailes*, 4006, *Corfield*, 5098-5100.

Should not be allowed in multiple articles of diet, *Stevenson*, 4832-33.

Desirable, unless proved absolutely harmless, in all food, *Corfield*, 5083-84.

## 71c. BORACIC ACID : Dairy Products :

Would curtail supply, *Williams*, 2148.

Absolute in France as to butter, if not also milk, save for export, *Williams*, 2218-20.

Interests of dairy farmers not prejudiced by action of Glamorgan County Council *Williams*, 2221.

## 71d. BORACIC ACID : Milk :

Recommended by Glamorgan County Council *Williams*, 2129.

Might in great measure be absolute if cleanliness assured and cold storage adopted, *Handford*, 2276, 2322.

Milk should not be boracised, *Handford*, 2302-4, 2319.

Should be absolute, *Mann*, 2606.

Not necessary, *Bell*, 2812, 2814, 2817.

In force at Guy's Hospital, *Stevenson*, 4798.

Of boracic acid in milk necessary; milk most largely used by children and invalids, *Tubb-Thomas*, 4932, 4934.

Would object to use of boracic acid and borax, especially in milk, *Starling*, 6944. Would not tolerate them in milk, 6954.

Of boracic acid in milk urged on account of harmfulness to children and also adults in ill-health, *Anderson*, 7189.

Advocated by Mr. Lockwood, *Womack*, 7507.

## 71e. BORAX : Bacon :

Would kill foreign competition, *Bennett*, 178.

Would result in attempt to cure bacon of poor keeping quality in Ireland, *Kellitt*, 32.

Would ruin Canadian, American, and Australian trade, *Bennett*, 156-60, 166-68; *Sinclair*, 936.

Would raise prices, *Bennett*, 163, 165.

Would check even continental products, save for immediate use, *Bennett*, 169-70.

Would result in return to salted meat, or in cessation of trade, *Bennett*, 175.

Would curtail trade, *Gregson*, 875.

Restriction in use for packing would hamper transatlantic trade, unless cold chambers were used, *Long*, 4659-60.

## 71f. BORAX : Competition :

Foreign would cease, *Bennett*, 178.

## 71g. BORAX : Ham :

Serious in absence of equally good preservative, *Kellitt*, 30.

## 71h. BORAX : Prices of :

Bacon would rise, *Bennett*, 163, 165.

## 71j. BORAX AND BORACIC ACID : Butter :

Would result in return to salt, *Trengrouse*, 703.

Would seriously affect the trade, *Clement*, 1527-28.

A little might be allowed in butter, *Stevenson*, 4832-33.

In butter used in France, *Hehner*, 5619 22.

Advocated by Mr. Lockwood, *Womack*, 7507.

71. PROHIBITION—*continued*.

## 71k. FORMALDEHYDE:

Needed, *Vasey*, 2046; *Hehner*, 5611.  
Should be prohibited in milk, *De Hailes*, 3966-70.  
Formalin should be prohibited until more is known of it, *Fisher*, 4767-68.  
Of formalin as a preservative should be absolute, *Starling*, 6940; *Halliburton*, 7548, 7550.

## 71l. PRESERVATIVES:

No general action in Birmingham, *Hill*, 2328-29.  
Preferred to declaration, *Boyce*, 2772.  
In Belgium and Germany, *Boyce*, 2741-42.  
Believed to exist in Austria, *Boyce*, 2745.  
Would seriously interfere with trade, especially dairy trade, and provision trade generally, *Bannister*, 3675-76.  
Substances of a poisonous character, or having active character as a drug should not be used in food, *Cassal*, 3794.  
Advocated, other than common salt, but including saltpetre in prohibition, *Cassal*, 3855-57.  
Of preservatives, or a "leave alone" policy the alternatives if limitation of maxima impracticable, *Foulerton*, 4153-54, and the former inclined to as regards chemical preservatives, 4155-56, that a total prohibition, 4157.  
Of preservatives in milk would not restrict supply, *Long*, 4572. Prohibition of preservatives should be enforced as regards substances the effect of which upon infants and invalids is not known, 4689. The effect should be determined prior to use, 4703-6.  
Of preservatives should be enforced in some cases, *Fisher*, 4727, and entirely in new milk, 4728, and new cream, fresh fish and fresh meats, 4745. No resolution passed by Society of Public Analysts, 4744.  
Advocated, *Stevenson*, 4832-33.  
Of preservatives not deemed essential if moderate quantities only used, *Blackwell*, 4873.  
Of saltpetre and pyroligneous acid desirable, *Corfield*, 5087.  
Salicylic acid, borax, boracic acid, and soda prohibited in Austria, *Corfield*, 5098-5100.  
Drugs should be avoided as preservatives in absence of knowledge as to action on the human economy, *Corfield*, 5121-22.  
Of preservatives or nothing advocated, for several reasons, including liability to repeated dosage, *Richmond*, 5754.  
Preservatives objected to on principle, *Dupré*, 5903, and indiscriminate admixtures of chemicals to food, 5904, irrespective of their effect, 5905.  
Preservatives should be prohibited, as injurious to cells of the system, *Grünbaum*, 6476, 6478; in other substances as well as milk; and including sodium sulphite, and boracic acid. Aseptic rather than antiseptic food should be aimed at, 6477.  
Advocated in food, *Starling*, 6986.  
Of preservatives advocated unless declaration of nature and amount be made, *Poore*, 7339-40.  
Of all foreign substances as admixtures in food to be desired, *Halliburton*, 7530, 7573-77. May be difficult but is ideal, 7578. Prohibition of formaldehyde should be absolute, 7548, 7550, also of salicylic acid, a dangerous drug, 7551-53. Nitrate of potash should be prohibited, 7576.

## 71m. PRESERVATIVES: Bacon and Ham:

Would affect producer and consumer, *Hudson*, 501.  
Would injure Irish and foreign trade, *Hudson*, 504.  
Enforced by France against America and withdrawn in 1899, *Hudson*, 505, 523.

## 71n. PRESERVATIVES: Butter:

Would affect keeping quality of Irish butter, *Dale*, 248

71. PROHIBITION—*continued*.71n. PRESERVATIVES: Butter—*continued*.

Would injure Irish trade, *Dale*, 256; *Shanahan*, 361-62, 412; *Hudson*, 538, and stop it, *Lovell*, 737, 765; *Riley*, 820.  
Would injure butter trade generally, *Lovell*, 764.  
In appreciable quantity at Newport (Mon.), *Jones*, 1309.  
Should be absolute, unless stringent rules as to quantities made, *Williams*, 2112, 2140.  
Desired, but deemed difficult, *Hehner*, 5609.  
Of preservatives would be a hardship on some butter makers for a long time, *Lough*, 6661, 6683-84. Harmful preservatives should not be used, 6664-67.  
Advocated by Mr. Lockwood, *Womack*, 7507.  
Would not permanently affect trade, *Dunn*, 3018-21.  
Home trade, some think, would be served thereby, *Dunn*, 3021.  
Dreaded by some, *Dunn*, 3022.  
Prices would not be long or greatly altered, *Dunn*, 3050, 3056.  
If enforced, Australian and Canadian butter would have to come frozen or in cold store, *Dunn*, 3057-58.  
Would lead to cold storage and frequent local demands as essentials in Ireland, *Dunn*, 3059.  
Medical considerations should outweigh those of trade, *Dunn*, 3060-61.

## 71o. PRESERVATIVES: Cream:

Would stop the sale, *Hudson*, 538.  
In appreciable quantity, at Newport (Mon.), *Jones*, 1309.

## 71p. PRESERVATIVES: Dairy Produce:

Desired by central and associated Chambers of Agriculture; motive mere guess work, *Carrington Smith*, 4487, 4554-57.  
Absolutely of preservatives in milk and butter advocated by Mr. Lockwood, *Womack*, 7507.

## 71q. PRESERVATIVES: Meat:

At Newport (Mon.), in appreciable quantity, in prepared meats, *Jones*, 1309.

## 71r. PRESERVATIVES: Milk:

In Newport (Mon.), *Jones*, 1309.  
Should be effected, *Voelcker*, 1716; *Cripps*, 1954, 1957; *Hehner*, 5608.  
Of boracic acid, would not raise price, *McFadyen*, 1773.  
Would not render fresh appearance and taste of milk difficult of attainment, *McFadyen*, 1774.  
Would not seriously affect urban supplies, *Walford*, 1909-10, 1928.  
In force in Austria, France, Germany, *Walford*, 1929.  
No reason against in England, *Walford*, 1930-31.  
Should as regards boron be absolute, *Williams*, 2112, 2140, 2169-70.  
Would affect small vendors, and might lead to monopolies or co-operative associations, *Williams*, 2245-56.  
Absolute in New York State, *Hill*, 2452-53; in Belgium, Austro-Hungary, and parts of Switzerland, 2454.  
Feasible in Birmingham, *Hill*, 2455.  
Should be prohibited by law, *Hill*, 2499, 2500, 2506.  
Should be absolute as to all, *Mann*, 2627-28; *Robinson*, 3335-38; *Hehner*, 5608.  
Needed, *Annett*, 2685.  
Continued experiments on kittens, yielding results like those of *Annett*, would suffice to prohibit preservatives in milk, *Boyce*, 2777-80.  
Would throw much milk on dealers' hand at present, *Brierley*, 3179-80.  
Boracic acid should not be added to milk, *Robinson*, 3336-37.  
Enforced for Guy's Hospital milk as unnecessary and inadvisable, *Stevenson*, 4800.  
Trade need not suffer, *Corfield*, 5088-89.  
Should be absolute, *W. C. Williams*, 5220.

71. PROHIBITION—*continued*.71r. PRESERVATIVES : Milk—*continued*.

Desired, *Hope*, 6888. Need not dislocate the trade, 6898.

Of preservatives has been held to be likely to advance price of milk, *Sorensen*, 7114. It need not do so, as evidenced by Copenhagen and Manchester, 7115.

Advocated by Mr. Lockwood, *Womack*, 7507.

## 71s. PRESERVATIVES : Wine :

Of salicylic acid in wines contracted for by Messrs. Gilbey, *Gilbey*, 4362, the acid also being prohibited in many wine producing countries, 4364, 4380, including France, 4370. Formaldehyde also prohibited by Messrs. Gilbey, 4368. Their wines tested for preservatives, 4396-4403 and footnote.

## 72. SALICYLIC ACID :

Should be entire, as a food preservative, *Cameron*, 2546-47; *W. C. Williams*, 5275-76.

Enforced in Austria, *Corfield*, 5098, 5100.

Would feel inclined to forbid use of salicylic acid, *Starling*, 6943.

Should be absolute; a dangerous drug, *Halliburton*, 7551-53.

## 73. PUBLIC ANALYSTS :

Should be placed in a position wherein they can speak on the authority of Governmental decisions on the question of the relation to health of added preservatives and colouring matters in food, *Cassal*, 3788.

## 74. PYROLIGNEOUS ACID :

Used as a preservative, *Corfield*, 5086.

Prohibition desirable, *Corfield*, 5087.

Used for painting "smoked herrings," *Poore*, 7385.

## 75. QUALITY :

## 75a. BACON : American :

Perfection has led to enormous increase of trade, *Bennett*, 173, 174.

## 75b. BACON : Canadian :

Superior to home products, *Bennett*, 137.

## 75c. BACON : Home :

Firmer and harsher in cure than Canadian, *Bennett*, 137.

## 75d. BUTTER :

Weather affects texture, *Lovell*, 739, 772.

Variety in creameries and factories due to handling, manufacture, method of supply, and defective water supply, *McCracken*, 2947-48.

"Mixtures" not made at Dunragit, *McCracken*, 2997.

Preservatised butter is insipid, *Long*, 4671.

## 75e. BUTTER : Australasian :

Finer winter article than Danish, *Lovell*, 730.

Freezing affects butter, *Cameron*, 6168. All New Zealand butter comes frozen, 6169, and defrosting tends to depreciation of the butter if not preservatised, 6171, 6202, 6295-97.

## 75f. BUTTER : Brittany :

More moisture than in Danish, *Trengrouse*, 635-36.

## 75g. BUTTER : Danish :

Remarkably good, *Kellitt*, 45-47.

Closer texture than Irish, *Dale*, 257.

Contains less water than Irish, *Dale*, 258.

Solid and free from moisture, *Trengrouse*, 635, 674-75; *Lovell*, 773.

Pasteurising has detracted from, *Lovell*, 729.

Has deteriorated, *Clement*, 1510-11.

Cannot compete with Normandy fresh, *Bannister*, 3504.

Finest under 2 per cent., very best class not over 1 per cent. of salt, *Bannister*, 3509-13.

Compares with old Irish butter, which was salty, and tub butter; Danish butter a substitute therefor, *Bannister*, 3517-20.

75. QUALITY—*continued*.75g. BUTTER : Danish—*continued*.

Flavour of Danish butter not lost by pasteurisation, but not so fine as English prime butter, *Long*, 4668; and cannot be made so fine, 4669.

Good, *Hehner*, 5602.

## 75h. BUTTER : Irish :

Secondary, *Kellitt*, 44.

Mild-cured largely prepared for English market, *Dale*, 263-64.

Much equal to Danish, *Dale*, 262.

Sold as cold store butter if more than a fortnight old, *Shanahan*, 465-68.

Relatively weak, *Lovell*, 737-40, 772.

Affected by food, *Lovell*, 738, 772.

Affected by wet weather, *Lovell*, 739-40.

Greatly improved of late, *Clement*, 1510.

Some equal or superior to Danish, *Bannister*, 3521.

Using Danish methods, Ireland could turn out equally good butter, *Long*, 4658.

## 75j. BUTTER : Normandy :

More moisture than in Danish, *Trengrouse*, 635-36.

Finer than Danish, *Lovell*, 730.

Fetches a higher price than Danish, *Bannister*, 3505.

Factory butter, *Bannister*, 3513-14.

## 75k. MILK : Boracised :

Often watered, but may have to with method of admixture, *Blyth*, 3442-43.

No change in milk effected by boracic acid, and hence the milk is fresh, *De Hailes*, 3970-71.

## 76. QUANTITY :

## 76a. BORACIC ACID :

Should be restricted, *Blyth*, 3468.

## 76b. BORACIC ACID in Bacon :

Four ounces per 100 lbs. of meat; sometimes 1 lb. used, *Prossor*, 569, 588-89.

One per cent. used and needed, *Greyson*, 877-80, 883-87.

Amount never determined, *Boseley*, 1046-44.

For mild-cured bacon and ham, from 4 ozs. to 1 lb. of boracic acid per 112 lbs. of meat, in powdered form, *Bannister*, 3649-53.

A little might be allowed, *Stevenson*, 4832-33. Found up to 62 grains per lb., *W. C. Williams*, 5169-70.

## 76c. BORAX ON BACON :

Canadian, 4 ozs. to 56 lbs., *Bennett*, 128-30, 184-87.

## 76d. BORACIC ACID IN BUTTER :

One per cent. kept butter nine months, *Sandes*, 107-10.

Has found  $2\frac{1}{2}$  per cent., *Lovell*, 787.

Three-quarters per cent., keeps butter for three or four months, *Dale*, 250, 282 290-91.

Less than one-half per cent. not sufficient, *Dale*, 287-89.

One-half per cent. required, *Shanahan*, 344-45, 354-55; and impressed on consignors, *Lovell*, 719-20; a necessary minimum, *Lovell*, 790-92; and ample, *Clement*, 1518.

Factories advised to use  $\frac{1}{2}$  per cent., *Trengrouse*, 646.

Traders at mercy of consignors, *Trengrouse*, 649.

Three per cent. highest known, *Trengrouse*, 678.

## 76e. BORACIC ACID IN CREAM :

One-quarter per cent. sufficient to keep for four to six days, *Hudson*, 515, 526-30.

More than one-half per cent. unnecessary, *Hudson*, 526-27.

## 76f. BORACIC ACID : Milk :

Traces of boracic acid found, *Wild*, 1442.

Has found  $\frac{1}{1000}$ , *Wild*, 1443.

In  $\frac{1}{1000}$  boracic acid keeps milk sweet for 24 to 48 hours, save in extreme heat, *Wild*, 1429.

Should not exceed 3 grains in a quantity to be consumed by a child, *Walford*, 1375.

Lowest found, 0.004 per cent., *Walford*, 1832.

Highest found, 0.105 per cent. *Walford*, 1832.

76. QUANTITY—*continued*.76f. BORACIC ACID : Milk—*continued*.

In separated milk, 28 grains per gallon, *Hill*, 2367.  
 From 21 to 126 grains per gallon found, *Hill*, 2334.  
 Reasons for differences vary, *Hill*, 2335.  
 Varying in Leeds, highest being 20 grains per gallon, *Cameron*, 2528-30.  
 Non-limitation would be difficult, *Boyce*, 2775.  
 Forty grains in milk would show meddling with milk, *Bell*, 2818.  
 Five grains per pint of milk quite safe, *Bond*, 3089.  
 Unnecessary and unusual to add 26 grains per pint, but nothing to prevent it, or repeated dosing of milk, *Bond*, 3099, 3100, 3102.  
 For young children  $4\frac{1}{2}$  grains per pint not safe, but poor children not likely to get that amount, *Brierley*, 3247-51.  
 Thirty-five grains per gallon sufficient, *Brierley*, 3175.  
 Eighty grains per pint found in December sample, *Blyth*, 3439-46.  
 Sixty grains per gallon found, *Bannister*, 3636.  
 Person on milk diet might consume nearly 20 grains of boracic acid, *Rideal*, 3692.  
 Quantity equal to 59 grains of boron-trioxide, and 101 grains of crystallised boracic acid found per gallon of milk, *Cassal*, 3816, 3865.  
 Smallest quantity determined equal to 19 grains per gallon of crystallised boracic acid, *Cassal*, 3817.  
 Would not allow 80 grains of boracic acid per pint, *Foulerton*, 4155.  
 Over 100 grains per gallon found, and conviction obtained, *Fisher*, 4736, 4762; boracic acid used recklessly, 4763-64.  
 Has found 20 grains in a sample, probably result of repeated dosage, *Kaye*, 5459-62.  
 Eighty grains to the pint of milk a very large dose, *Attfield*, 6560-61; but probably an isolated case, 6562.

## 76g. BORAX IN BUTTER :

Infinitesimal, *Bennett*, 150.  
 Heavily boraxed butter would be rejected, *Bennett*, 211-13.  
 Excessive quantity needed to flavour butter to point of rejection, *Bennett*, 215, 218.  
 No proceedings known on account of excess of weight, *Bennett*, 221-26.

## 76h. BORAX AND BORACIC ACID IN BUTTER :

Only minimum requisite amounts used, *Lovell*, 718, 737.  
 One-half per cent. keeps butter three or four days, *Lovell*, 725, 783, 793.  
 Analyses for, frequent, *Lovell*, 775.  
 Samples found to yield 0.71, 0.74, and 1.3 per cent. (over 90 grains per lb.), *Jones*, 1309, 1322.  
 Limit of use not determined, *Jones*, 1310, 1312, 1385.  
 Percentage of 0.25 said to be needed, *Walford*, 1861-62.  
 Dr. Dyer found an average of  $\frac{1}{2}$  per cent., and in  $\frac{1}{5}$  boracised samples over 1 per cent., *Fisher*, 4717-21.  
 Preservatised with 0.77 per cent., *Kaye*, 5458.  
 Daily dosage in butter not likely to be large, *Kaye*, 5507-8.  
 Butter going to Great Ormond Street Hospital has been found to contain 17.4 to 47.6 grains of borax per lb., and has been given to children, no ill-results noted, *Still*, 6814.  
 Very little taken, and that only by a few, 6815.

## 76j. PRESERVATIVES : Milk :

*Quantity found :*

From  $13\frac{1}{2}$  to 210 grains found per gallon, *Williams*, 2116-18, 2121.

76k. *Quantity used :*

One half to one oz. per 16 gallons, *McCracken*, 2878-79.  
 Need not exceed 30 grains or so per gallon, *McCracken*, 2928.

76. QUANTITY—*continued*.76j. PRESERVATIVES : Milk—*continued*76k. *Quantity used*—*continued*.

One hundred grains per gallon of dissolved preparation outside Southampton, in summer only, *Brierley*, 3174, 3177.  
 Larger amounts than vendors declare to be necessary, *Brierley*, 3212-13.  
 Should be restricted, *Rideal*, 3693.  
 Liable to be in needless quantity, *Cassal*, 3812.

## 76l. PRESERVATIVES : Quantity :

An important factor, *Walford*, 1873.  
 Useful, questionably harmless, *Walford*, 1874.  
 Maximum limits should be insisted on, *Vasey*, 2058, 2076.  
 Should be restricted, *McCracken*, 2931.  
 Higher proportions than  $\frac{1}{5000}$  of formaldehyde and  $\frac{1}{5000}$  of borax and boracic acid mixture might be taken; question one of idiosyncrasy; these amounts safe, if declared, for majority of persons, and would suffice for trade purposes, *Rideal*, 3691, 3694-96.

## 76m 1. PRESERVATIVES : Butter :

Weighed very exactly, *Sandes*, 97; same proportion whole year, *Sandes*, 104; one-half per cent. not enough, *Shanahan*, 343; three-quarters per cent. requisite, *Shanahan*, 375-78.  
 One-half per cent. sufficient, *Hudson*, 492; and never exceeded, 499.  
 One per cent. ample, *Clement*, 1518; 17 grains per lb. enough, *Williams*, 2129.

## 76m 2. PRESERVATIVES : Butter :

*Quantity found :*

From 1 to 112 grains per lb., *Williams*, 2125, 2125\*.  
 Very small quantity to 1 per cent. *Hehner*, 5566.

## 76n. PRESERVATIVES : Cream :

Should be limited and standardised, *Voelcker*, 1749-50.

## 76o. PRESERVATIVES : Milk :

Should be limited and standardised, *Voelcker*, 1749-50.  
 If useful, might be distinctly dangerous *McFadyean*, 1752.

## 77. RENNET :

One sample found to contain boracic acid preservative, *Voelcker*, 1685-86.

## 78. RESTRICTIONS AS TO USE OF PRESERVATIVES :

## 78a. BORACIC ACID : Indiscriminate Use :

Objectionable in food, *Walford*, 1883.  
 Prohibition of indiscriminate use of boracic acid should be enforced if large doses are put into milk, *Attfield*, 6562-65.  
 Should not be used indiscriminately in milk, *Anderson*, 7207.

## 78b. BORACIC ACID : Butter :

*Stipulations :*

None as to factory butter, *Dale*, 321-25.  
 None, *Trengrouse*, 649.

## 78c. PRESERVATIVES : Indiscriminate Use :

Legislation as to undue use advocated, *Lovell*, 722, 724.

## 78d. PRESERVATIVES : Restrictions :

Restriction to one preservative material and to a limited quantity should be enforced on vendors, and use allowed only in three hot months of the year, *Long*, 4689.  
 Restriction on the use of preservatives desirable, *Fisher*, 4726, 4737; boracic acid in milk being instanced, 4728; and a superior limit called for, 4732; though some difficulty might arise in cases, 4733-35; and especially as to formaldehyde, 4741-42; at present, 4752; limit should be placed on preservatives on salted and preserved meats (as ham and bacon) and fish, 4745.

78. RESTRICTION AS TO USE OF PRESERVATIVES—*continued*.78d. PRESERVATIVES: Restrictions—*continued*.

Regulation required of quantities of preservatives permissible, in gradually diminishing amount in butter, as facilities to obviate their use come in, *Hehner*, 5605-6.

Restriction of quantity of preservatives by limitation inoperative, *Richmond*, 5753-54.

Restriction rather than declaration of preservatives advocated, pending prohibition, *Lough*, 6662; latter might handicap the trade, 6662-63. Would like to know if he were taking a harmful preservative, 6669-72. Consumer has a right to know, 6673-75; but not as to butter only, 6675.

Indiscriminate use should be remedied, *Hutchison*, 6722, 6749.

Chemical preservatives in food studied, *Brunton*, 7425-26. Use should be regulated, because of double danger of undue use, 7427.

Preservatives not strongly objected to, *Womack*, 7478; but regulation desirable, 7479.

## 78e. PRESERVATIVES: Unrestricted Use:

A great danger, *Voelcker*, 1676.

Indiscriminate and reckless use of preservatives objectionable; 150 grains of salicylic acid found per gallon of British wine, *Hope* 6842, 6923.

## 79. SALE OF FOOD AND DRUGS ACT:

## ADMINISTRATION:

Sampling not extensive in Newport (Mon.) *Jones*, 1401-4, 1406.

In Cardiff, population 186,000 persons, 600 samples of food and drugs analysed annually, *Walford*, 1821-24, 1909.

Analysis made of vended samples of milk and butter in County Glamorgan, *Williams*, 2113-14.

Bacon not an "article of food," *Brierley*, 3199, 3200.

Law as it stands presents practical difficulties as to preservatives and colouring matters in the public interests, such interests being the reason for the Sale of Food and Drugs Act, *Cassal*, 3794.

Trained inspectors necessary for the obtaining of average samples of food, *Hope*, 6875-77.

## 80. SALT:

A food, and common to the body, *McFadyean*, 1776; *Mann*, 2628.

A feeble preservative, less potent than boracic acid, *McFadyean*, 1776-77.

Cannot compare with boracic acid as a preservative, *Mann*, 2628.

Bulk for bulk more harmful than boracic acid, *Bell*, 2791-92.

A constituent of the human body, *Corfield*, 5085.

A food, *Hehner*, 5637-38.

Salt scarcely more a food than boracic acid, *Attfield*, 6549; but it is a component of the human body, 6550. Salt betrays its presence in food, 6551.

## 80a. BACON:

Washed off after cure, *Kellitt*, 15.

American formerly cured by, and packed in, *Kellitt*, 15.

Cannot be extracted by steeping, *Kellitt*, 15.

Excess reduced by use of borax, *Kellitt*, 15, 73-74.

Used in curing, *Kellitt*, 16.

Conceals defects, *Trengrouse*, 654-57.

American, replaced by boraxed bacon, *Kellitt*, 15, 29, 33-35.

Led to complaints, as to excess of salt, *Kellitt*, 15.

People will not eat, *Kellitt*, 29, 31.

Held in check by borax, *Bennett*, 145-47.

Salted goods not appreciated, or saleable, *Bennett*, 176-78; *Prossor*, 559-60; *Trengrouse*, 665.

Much would be needed if preservatives were not used, *Prossor*, 570.

Replaced by preservatives, *Gregson*, 838; but used for packing 25 per cent. of American and Canadian meats, *Gregson*, 859-61.

80. SALT—*continued*.80a. BACON—*continued*.

Cost, 30s. per ton, *Gregson*, 888.

Packing renders meat too salt, *Gregson*, 871, 875, 896.

Absorbed by bacon, *Gregson*, 897, 931-33.

Percentage used in cure, 5 to 10, and even 20 per cent. in Irish bacon, *Gregson*, 927-28.

A good deal runs to brine, *Gregson*, 928.

No Canadian meat comes salted, *Sinclair*, 936.

Hurtful to mill hands, *Davidson*, 1599, 1600.

When it was used, less eaten, and more cheese eaten, *Davidson*, 1601-3.

## 80b. BUTTER:

Heavily salted not now in demand or saleable, *Kellitt*, 43; *Dale*, 241-42; *Hudson*, 493-94; *Clement*, 1520.

In excess, as injurious as borax, *Kellitt*, 43.

Three lbs. to 112 lbs. of butter, *Sandes*, 79.

Almost entirely replaced by preservatives, *Sandes*, 80; *Dale*, 243.

English customers no longer take heavily salted Irish butter, *Sandes*, 80.

Heavily salted butter contains six to seven per cent. of salt, *Sandes*, 84.

Return to heavily salted butter impossible, *Sandes*, 89.

Price lower than unsalted butter, *Sandes*, 94, 105.

Some people prefer salt flavour, *Sandes*, 85, 86.

Needs to be evenly distributed, *Shanahan*, 387.

All heavily salted, years back, especially Irish butter, *Hudson*, 493-94.

Margarine would replace insistence on it, *Clement*, 1520.

Vastly different from fresh butter, *Clement*, 1556.

Should alone be added, on physiological grounds, *McFadyean*, 1756, 1758.

Heavily salted, not now pleasing to public taste, *McFadyean*, 1760.

Some samples preservative, *Williams*, 2127-28.

In less favour than formerly, *McCracken*, 2857.

Tends to evaporate, *Gibson*, 6363.

## 80c. BUTTER: Borax:

Held in check, *Bennett*, 145-47.

## 80d. BUTTER: Danish:

More than in Irish, *Dale*, 265.

One per cent. or more, *Trengrouse*, 630, 654.

No fresh butter imported, *Lovell*, 717, 771.

Salted to taste, *Eiley*, 833.

Contains a little salt, *McCracken*, 2859-60.

Only, contained, *Bannister*, 3504.

About two per cent., but amount varies, *Bannister*, 3507-8.

Most salted to some extent, some not salted, some  $\frac{1}{2}$ , but most one per cent., *Faber*, 4221-22.

Danish butter contains, some of it  $2\frac{1}{2}$  per cent. and some three and four per cent. of salt, *Gibson*, 6361-62.

## 80e. BUTTER: Irish:

Used, *Dale*, 275.

Not in large amount, *Dale*, 276.

Same as Normandy, *Dale*, 265.

None in fresh butter, *Dunn*, 3028.

Some old butter was not heavily salted, made in summer, without abnormal quantity of water, with exception, *Bannister*, 3522-31.

## 80f. BUTTER: Normandy:

Only salted butter imported 40 years back, *Lovell*, 713.

## 81. SALTPETRE:

Bulk for bulk more harmful than boracic acid, *Bell*, 2791-92.

Would spoil milk, *Bell*, 2819.

Used as a preservative, *Corfield*, 5086.

Prohibition desirable, *Corfield*, 5087.

## 81a. BACON:

Used in curing, *Kellitt*, 16.

(See also under Cure.)

## 82. SANITARY CONDITION OF DAIRY FARMS:

Chief London agencies look to it, *Foulerton*, 4108-11.

Factor in determining keeping quality of milk, *Foulerton*, 4112.

Gross neglect of ordinary precautions and sanitation where preservatives used, *Tubb-Thomas*, 4948.

Sanitary improvement in rural districts put back by use of preservatives, *Tubb-Thomas*, 4946, 5027. Some farms in such a state as to render milk impossible of delivery without preservatives, 5027-32. Dairies, &c., order not generally enforced, 5033-36. Proper water supply would result from enforcement, 5037-38.

Precautions adopted by Aylesbury Dairy Co. to secure proper milk supply from farmers, *Hattersley*, 5818-19, and farms inspected, 5820.

## 83. SLIME :

## BACON :

Obviated by borax, *Kellitt*, 15, 73, 74; *Gregson*, 871, 896.

Sprinkled borax remains dry, *Gregson*, 929.

Moisture prevented by borax, *Kellitt*, 11, 12, 23; *Prosser*, 598, 607-9.

## 84. SODIUM FLUORIDE :

Not a good anti-fermentative, *Boseley*, 1046.

## 85. SODIUM HYPOSULPHITE :

Taken from 15 to 45 grains per diem, prevented discomfort attending fibrous foods, but at times unpleasantness resulted, *Attfield*, 6539-44, but experience not of same value as that with boracic acid, 6545.

Sulphite of sodium in meat heard of, 6913, but not inquired about, *Hope*, 6914.

Irritant properties of sodium sulphite comparable with boracic acid, *Starling*, 6979. Has never prescribed the sulphite, 6980.

## 86. STANDARD :

## 86a. BORACIC ACID IN BUTTER :

Needed, *Trengrouse*, 660, 702.

## 86b. MILK :

Three per cent. of fat stipulated for, and all milk tested by Manchester Pure Milk Supply Co.; average 3.5, *Sorensen*, 7065-70. Has fallen to 2.7 on a single day in August, 7071.

Evening and morning milk differ in quality, *Sorensen*, 7093-96, and evening milk may be diluted to quality of morning milk, 7097-98.

## 86c. PRESERVATIVES :

Desirable, limiting use, *Vasey*, 1997-2001, 2003, 2050-51, 2058, 2076.

Standardising of fresh preservatives advocated, *Cameron*, 6242.

Standardising of preservatives desired, *Hutchison*, 6723.

## 87. STERILISATION :

Milk should be sterilised, and a little boracic acid added, *Bell*, 2847-48.

Not sterilised at Dunragit Creameries, *McCracken*, 2894-98.

Digestibility of sterilised milk said to be less than ordinary, *Foulerton*, 4161-62.

Sterilisation would help to keep milk, *Foulerton*, 4070, especially if bottled, 4071, but then expensive, 4072, as illustrated by Paris hospital practice, 4073, but expense mainly a matter of management, 4074-75. Sterilisation would be beneficial in the interests of the community, 4187, but its destructive effect on the tubercle bacillus doubted, 4188-93, but the heating of milk to 65° Centigrade would be a benefit, 4194. If practicable sterilisation would be the best thing, 4198.

Sterilisation practised by witness, *Long*, 4594; on small scale, 4599, but in places on a very large scale, 4600; process described 4595-98. Bottle cleansing is a trouble, 4601. Bottled milk used in Switzerland 4602. Milk cannot be

## 87. STERILISATION—continued.

tampered with in transit, 4603, and delivery is less frequently needed, 4604. Cleansing of bottles more difficult than of cans, 4697-4701, unless daily service in question, 4702. Bottling of milk on a large scale need not raise the price, 4707-9.

Held to tend to innutrition, *Stevenson*, 4804.

Milk should be strained, cooled, and sterilised, *Tubb-Thomas*, 5039-40.

Refrigeration, sterilisation, and pasteurisation on different footing to preservatives in milk, *Kaye*, 5499-502. Recommends sterilisation of milk, 5559. Doubts its indigestibility, 5560. Growing in use in Ripon, 5561.

Some nursery milk delivered in bottles, *Hattersley*, 5884-86, from special farms, 5893. Bottled milk entails expense, 5887-88. Paris has bottled milk at 6d. per quart, 5889. Copenhagen gets both bottled and can milk, 5890-92.

Sterilised milk demand increasing, *Hattersley*, 5784. Milk heated to 212° F., 5785, and fairly large trade done by Aylesbury Dairy Co., 5786. Delivered in bottles, 5885.

Salicylic acid as ineffective as boracic acid as to milk sterilisation; milk practically saturated, ~~not~~ not sterilised, *Blaxall*, 6070.

Sterilisation preferred as an alternative to chemical preservatives, *Hope*, 6899. Infantile scurvy never heard of in association with sterilisation, 6900-1. Evidence to the contrary as to sterilised humanised milk, 6902-7.

Sterilised milk not likely to produce scurvy—that is, mal-nutrition, *Starling*, 6946. Infantile scurvy said to prevail most in higher classes, 6947-48, who use most sterilised milk, 6949, hence cause and effect presumed, 6950-52. No direct experiments made, 6953.

With cooling of milk would obviate need for preservatives, *Brunton*, 7444.

Sterilised milk held by some to be injurious, not so held by witness, *Brunton*, 7445, but our knowledge may be defective, 7446-47, the raising of milk for a short time to 180° F. being in question, 7448.

Sterilised milk not known to be harmful, *Halliburton*, 7580-82.

## 87a. BUTTER :

Not essential, *Voelcker*, 1743-47.

(See also Pasteurisation.)

## 88. STRYCHNINE :

Injurious, *McFadyean*, 1801-2.

## 89. SUGAR :

Defensible in fruits, *McFadyean*, 1776.

## 90. SULPHUROUS ACID :

Not to be classed as an antiseptic with formalin; it keeps changing into a sulphate, a natural constituent of beer, and is not dangerous, *Bannister*, 3672-74.

Found in British wines, vinegar, pickles, &c., and probably harmless as used, *Fisher*, 4746.

(See also under Beer.)

## 91. TRADE :

## 91a. BACON :

Week to week, *Davidson*, 1620-21.

Bacon brought in as is fresh meat would not be in same condition as borax-packed bacon, *Bannister*, 3501.

English bacon trade very small compared with American trade, *Harris*, 6015-17.

## 91b. BACON, American :

Began 50 years ago, in crude form, *Benne* 173.

Increase enormous of late years, *Bennett*, 173 174.

## 91c. BACON, Home :

Small, because unpopular, *Bennett*, 131-32.

Relation to imported produce small, *Benne* 161-62.

Small compared with American trade, *Harris* 6015-17.

## 91. TRADE—continued.

## 92a. BUTTER :

Many changes in last 50 years, *Hudson*, 492.  
Long experience, *Lovell*, 706-7.  
Greatly developed of late, *Lovell*, 708-11.  
People do not want preservatised butter,  
*Long*, 4658.

## 92b. BUTTER, Australasian :

Increasing, at lower price than Danish, *Tren-  
grouse*, 650.  
Introduction has brought down Danish prices,  
*Trengrouse*, 702.  
Seasonal only, *Davidson*, 1623-24, 1626-28.  
Output sometimes small, by reason of drought,  
*Davidson*, 1630-31.  
New Zealand butter output increasing, *Came-  
ron*, 6155, 6214-15, and quality steadily  
improving, 6156, owing to instruction and  
inspection, 6157. Small in comparison  
with colonial trade generally, 6228-33.  
Retail same as export, 6247.

## 92c. BUTTER, Brittany :

Chiefly with London, *Trengrouse*, 692.

## 92d. BUTTER, Danish :

All year round trade, supplanted Irish sea-  
sonal trade, *Bannister*, 3534-35.  
Trade in Danish butter not affected by pre-  
servatised French and Irish butter, *Faber*,  
4224. It is about  $\frac{1}{2}$  of foreign butter trade  
of England, 4316.  
Agricultural pursuits occupied about half  
Danish population, *Faber*, 4244-47, in 1890,  
about  $\frac{2}{3}$ ths, footnote to 4247.  
All year round, *Gibson*, 6318-19.

## 92e. BUTTER, Irish :

Regaining lost ground, *Dale*, 261, 297.  
Increasing, *Hudson*, 538 ; *Gibson*, 6396.  
Has increased threefold in recent years,  
*Hudson*, 542-44.  
Hampered by manufacture in small quantities,  
*Lovell*, 750.  
Foreign butter a competitor, Australasian  
butter takes the place of the old Irish  
winter trade butter, *Dunn*, 3016, 3050.  
Lost the market by being only a seasonal  
trade, *Bannister*, 3533-35.  
Mainly summer trade only, *Gibson*, 6317. It  
need not be so, 6323-24, as witness has  
endeavoured to show farmers, 6325, with  
some success, 6326.  
Milk in Ireland in winter months sent into  
towns, thus interfering with butter trade,  
*Gibson*, 6317, 6321-22.  
Calving cows largely housed in Ireland in  
winter, *Gibson*, 6320. Irish trade such  
that butter must keep for months, 6353,  
6394, and does.

## 92f. BUTTER, Normandy :

Chiefly with London, *Trengrouse*, 692 ; entirely  
a South England commodity, *Riley*, 827.

## 92g. CANADIAN HOG PRODUCTS :

Increase enormous in last ten years, *Bennett*,  
130, 233-36.

## 93. TRANSIT :

## 93a. BUTTER :

From varying parts to Aylesbury Dairy Co.,  
*Boseley*, 1023, 1028-29.  
Can be brought long distances without pre-  
servatives, *Jones*, 1309, 1315, 1339-41.  
Transit of butter in Ireland the curse of the  
trade, *Lough*, 6637-6639. Redress hoped  
for at the hand of the new Agricultural  
Board, 6638. No traders' rolling stock in  
Ireland, 6640. Procedure for compensation  
very unsatisfactory, 6641. Matters in Ire-  
land worse than in Denmark, 6687.  
Transit of butter in refrigerator cars in New  
Zealand, *Sorensen*, 7164, and of butter and  
milk, also in Denmark, 7165-68. None  
such in Manchester, 7169-70.

## 93b. BUTTER, American :

Used to spoil it, prior to use of preservatives,  
*Lovell*, 712

## 93. TRANSIT—continued.

## 93c. BUTTER, Australasian :

On boardship five to six weeks, *Trengrouse*, 677.  
Comes to England from December to May  
or June, *Cameron*, 6216. Butter reaches  
consumer in England in 11 weeks from  
manufacture, 6248-49. Complaints of butter  
have been made, but kind of butter no  
known, 6250-51.

## 93d. BUTTER, Irish :

To a distance in hermetically sealed tins, *Dale*,  
272.  
To England from Cork practically similar to  
Denmark, *Dale*, 293-96.  
To Scotch market from Western Ireland three  
days ; to London four days, *McCracken*,  
2942-45.  
Transit of butter from New Zealand under  
best possible conditions, *Gibson*, 6331, from  
Ireland and in England, under very worst  
possible conditions by railways and steam-  
ship companies, 6331-33, 6343-45 ; many  
complaints, 6334, and practically no redress,  
6335. Specific complaints instanced, 6332-  
33, 6337-42. Danish and Swedish Govern-  
ments see to such a matter, 6336, and get a  
better service, 6386-89. No improvement  
in handling the butter by railway companies,  
6346-49. Improved transit needed, 6397.

## 93e. CREAM :

Partly from Wiltshire for Aylesbury Dairy Co.,  
*Boseley*, 1038.

## 93f. MILK :

Long distances render preservatives necessary,  
*McCracken*, 2869.  
Some comes from Scotland to London,  
*McCracken*, 2872-74.  
Of skim-milk from Scotland to London, costly,  
*McCracken*, 2911-12.  
Related to use of preservatives, *Blyth*, 3480-  
81.  
Transit to London practically limited to two  
trains daily, from a distance, and evening's  
milk 12 and morning's milk 24 hours old on  
reaching consumer, *De Hailes*, 3903-17,  
3948.  
Aylesbury Dairy Co. draw milk from a dis-  
tance without preservatives, *Foulerton*,  
4158-59.  
Sent to London from Hampshire and Hert-  
fordshire, *Long*, 4611-13.  
Transit of milk by rail may need improve-  
ment, 4970. At present harm may accrue,  
*Tubb-Thomas*, 4971-73. Matter easy of  
rectification, 5045.  
No difficulties of transit by rail, *Hattersley*  
5778. Milk occasionally sent in a fish truck,  
5779-80. Churns sealed during transit,  
5824-26. Trade of Aylesbury Dairy Com-  
pany  $1\frac{1}{2}$  million gallons yearly, 5841-43,  
from 50 farms, 5844, averaging 50 miles  
away, 5845. Some 100,000 persons supplied  
annually, in 14,000 households, 5848-53,  
over a wide London area, 5894-95. Milk  
comes to Paddington and Euston, 5896-97.  
Many poor class customers, 5898.

## 94. UNSALTED :

## 94a. BUTTER :

One lb. of preservative to 112 lbs. of butter  
and mild salted butter with 3 lbs. of salt  
in addition, *Sandes*, 79.  
Mild cured still marketable, *Sandes*, 84.  
Must needs be good to fetch its price, *Sandes*,  
94, 105.  
Price higher than salt butter, *Sandes*, 94, 105.  
Little made in winter, *Sandes*, 105.  
Would not keep for 24 hours in hot weather  
without preservative, *Dale*, 265.  
Now in demand, *Lovell*, 710.

## 94b. BUTTER, Irish :

Now sent, *Lovell*, 741-44.

## 95. WATER :

## 95a. BUTTER, Irish :

From 12 to 13 per cent., *Dale*, 306-7 ;  $13\frac{1}{2}$  to  
15 per cent., *Lovell*, 770 ; 14 to 15 per cent  
*Dunn*, 3039.

95. WATER—*continued*.95a. BUTTER, Irish—*continued*.

Seasonal variations, from 10 to 23 per cent., *Dale*, 308-9.  
 No standard, *Dale*, 308-9.  
 Excess may lead to preference for Danish butter, *Dale*, 310-12.  
 More than Danish, *Lovell*, 767.  
 Cannot be reduced to Danish proportion, *Lovell*, 770.  
 With less moisture would surpass Danish, *Clement*, 1510.  
 Not so dry as Danish or Australian, *Dunn*, 3024, 3037-38.  
 Question investigated by Munster Agricultural Institute, *Dunn*, 3024, 3037-38.  
 If 18 per cent., butter not Cork-branded; would betoken negligence; if 20 per cent. prosecution used to and might still ensue, *Dunn*, 3040-46.  
 Pressing out requires great care in hot weather; but very cold water in skilled hands would ease matters, *Dunn*, 3047-49.  
 Same as in good butter, *Long*, 4644.

## 95b. BUTTER, Scotch :

Amount in Scotch butter unknown; less than in Irish butter; dry as Danish butter, *McCracken*, 2994-96.

## 96. WATER SUPPLY TO FARMS :

Many farms have none for cooling milk so as to render preservatives less needful, *McCracken*, 2924.  
 Should be proper in all cases, *Cassal*, 3863-64; *Kaye*, 5524-26.

## 97. COLOURING MATTERS :

Not troubled about, *Jones*, 1407; not specially worked at, *Wild*, 1487; used, but no personal knowledge of, *Walford*, 1922-26; not studied, *Cripps*, 1974; not studied apart from copper, *Munn*, 2623-25; not studied, *Bond*, 3138-39; not much studied, *Corfield* 5133-34.  
 Studied a little, *Hill*, 2479-80.  
 Present difficulties, *Cassal*, 3838-41.  
 List handed in, *Carrington-Smith*, 4463-66 (App. No. 11).  
 Some named, *Fisher*, 4778.  
 Chromate of lead and oxide of iron known to be used, *Fisher*, 4780.  
 Colouring matters of late have undergone change for the better, especially in sweetmeats, no noxious dyes being now found, *Stevenson*, 4837, nor for 20 years past, 4838-39. Regulation a question of expediency. Colourings varying constantly, 4842. They should be scheduled, after experiments, 4843, which are essential, 4844-45.  
 Colouring matters not subject of evidence by St Bartholomew's Hospital, *Womack*, 7509.

## ANALYSES :

Often difficult by reason of small sample, *Blyth*, 3364, 3369.  
 Almost any aniline dye can be detected, in relatively small quantity, *Blyth*, 3367-68.  
 Dyeing test to silk often required to detect colourings, *Cassal*, 3848.

## ANCHOVY SAUCE :

Used, *Copeman*, 1178.  
 Red earth used for essence of anchovies, *Blackwell*, 4889.

## ANILINES :

Aniline dyes rare years ago; but for last 8 or 9 years sweetmeats and other articles coloured with coal-tar colours, *Blyth*, 3351-53, 3366.  
 Aniline colourings not found in dangerous proportions in any one article; but accumulated effects of many articles so coloured might injure a child, *Blyth*, 3358.  
 Becoming more general for milk, *Boseley*, 1098-1100.  
 Used at times for milk, *Hill*, 2485-86; *Cassal*, 3844.  
 Used in sweets and peppercorn, *Voelcker*, 1666-69.

97. COLOURING MATTERS—*continued*.ANILINES—*continued*.

No doubt used in dairy produce, *McCracken*, 2958-59, 2967-77, 2981-90, 3000, 3001.  
 Used in vegetables, *Blyth*, 3356.  
 Used for confectionery and sugar, *Cassal*, 3847-48.  
 Now much used, in very small quantity; not sufficient to harm, *Hehner*, 5568-70.  
 Used in dairying trade, in extremely small amount, about 150000, *Richmond*, 5760, 5763-64.

## ANNATTO :

Never analysed, *Boseley*, 1078-79.  
 Only colour used by Aylesbury Dairy Co., *Boseley*, 1097, 1102-4; and its nature and constitution described, *Richmond*, 5759.  
 Spanish, used in butter and cheese, *Copeman*, 1178, 1282.  
 Non-injurious, *Copeman*, 1178, 1282.  
 Simplest colouring agent; used in butter as well as milk, *Brierley*, 3284-86.  
 In chief use in dairy produce, *Boseley*, 1050; *McCracken*, 2956-57; also with anilines, 2983-84; *Carrington-Smith*, 4467-72.  
 Harmless, *Long*, 4684.  
 In most milk, *Sorensen*, 7083.

## BACON AND HAM :

Saltpetre used, *Hudson*, 508.

## BEER :

Only natural colouring found, *Blyth*, 3419.

## BEVERAGES :

Temperance drinks coloured, *Fisher*, 4779.

## BUTTER :

Added, *Dale*, 281, 326.  
 Irish butter only needs in winter, *Dale*, 327.  
 Fluid used, *Dale*, 328-29.  
 Use of saffron, *Dale*, 328-29, 334.  
 Tested; name not known, *Dale*, 330-33.  
 Use of annatto, *Dale*, 334; *Trengrouse*, 638-39.  
 Best retentive colour decided on, *Dale*, 334.  
 Vegetable only, *Dale*, 336-37.  
 Aniline dyes not used, *Dale*, 337.  
 Used only in winter, *Hudson*, 531.  
 Needed only to satisfy local public demands, *Lovell*, 734-37.  
 Not usually fraudulent, *Voelcker*, 1691.  
 Butter changes colour naturally, *Voelcker*, 1692.  
 Going out; demand for highly-coloured butter declining; only saffron and annatto known, *Dunn*, 3030-31.  
 Matter behaving like methylorange commonly used for low-class butters, *Brierley*, 3279.  
 Inferior butter made to look like good butter, *Brierley*, 3281.  
 Some unobjectionable, *Cassal*, 3838-41.  
 Not used by witness and not needed, *Carrington-Smith*, 4454-55, 4473, 4481-82.  
 Colour of butter affected by food and breed of cattle, *Carrington-Smith*, 4482-86.  
 Used, and colour affected by breed of cattle, *Long*, 4684.  
 Not fraudulent, *W. C. Williams*, 5353-57.  
 Much used in South England; some uncoloured in Midlands, *Hehner*, 5567.  
 Annatto in solution of cotton-seed oil, *Boseley*, 1050.  
 Not needed for New Zealand butter, *Cameron*, 6217-22.  
 Debatable point in Ireland. Witness holds it essential to meet varying local tastes, *Gibson*, 6364, 6369-70. Colour cannot be kept constant by food; it can by having Jersey cattle, 6366-68. Colouring enables margarine to be sold as butter, 6364, 6370.  
 Hardly ever used in creameries, *Lough*, 6648.  
 Some dairies use annatto in very small quantities, 6649. Winter butter nearly same colour as summer butter, 6649-50, 6652, with mixed breeds of cattle, 6651; no Channel Islands cattle in question, 6652.  
 An error in scalding may render annatto necessary, 6652. No great difficulty as to colour, 6653.  
 Uniformity of colour means artificial coloration, *Poore*, 7369.

## 97. COLOURING MATTERS—continued.

**BUTTER : Nature :**  
 Danish colouring, *Shanahan*, 370-74.  
 Annatto, dissolved in cotton-seed oil, by  
 Aylesbury Dairy Co., *Boseley*, 1101.

**BUTTER : Quantity :**  
 Small, *Shanahan*, 371-72.  
 Standardising needed, *Richmond*, 5762.

**BUTTER : Why used :**  
 To secure uniform colour, *Shanahan*, 369.

**CARMINE :**  
 Used in France for glacé and crystallised  
 cherries, non-injurious, *Copeman*, 1178.

**CHEESE :**  
 Annatto used, largely, *Trengrouse*, 643-45.  
 Used only to satisfy local public demands,  
*Lovell*, 734-37.  
 Some markets will not take coloured cheese,  
*McCracken*, 2962.  
 Everybody knows cheeses are coloured,  
*McCracken*, 2969.  
 Colouring favoured by Staffordshire Chamber  
 of Agriculture, *Carrington Smith*, 4488-  
 4503.  
 Used, for purposes of price, and to supply  
 local demand, annatto being in question,  
*Carrington Smith*, 4457-62, 4477-80.  
 Used in some, *Long*, 4684.  
 Matter of public fancy, *Long*, 4687-88.  
 Unnecessary, save to meet public demand,  
*Hudson*, 533.  
 Some unobjectionable, *Cassal*, 3842-43.  
 Has no opinion to offer as to the colouring of  
 cheese, *Hattersley*, 5816-17.  
 Annatto, exclusively, *Cameron*, 6222-25.

**CHEESE : Nature :**  
 Annatto said to be used to meet public demand,  
*Hudson*, 534-36.

**CHLOROPHYLL :**  
 Not a successful substitute for copper sulphate,  
*Copeman*, 1188.

**CHROMATE OF LEAD :**  
 Used to be found in confectionery, *Hill*,  
 2485-86.  
 Known to be used, *Fisher*, 4780.

**CLASSIFICATION :**  
 Scheduled in Belgium, *Blyth*, 3399, 3400.  
 Scheduling should, and could be made in this  
 country, *Blyth*, 3404-6.  
 Would have to be made on general principles,  
*Blyth*, 3411.

**COCHINEAL :**  
 Used freely in jams, jellies, &c., *Copeman*,  
 1176.  
 Non-injurious, *Copeman*, 1176.  
 Used in preserved cherries, *Copeman*, 1178.

**COCOA :**  
 None found, *W. C. Williams*, 5379.

**COFFEE :**  
 None found, *W. C. Williams*, 5379.

**CONFECTIONERY :**  
 Complete list, *Boseley*, 1049, 1064-70 (App.  
 No 18).  
 Hoffman's violet used for sweets, *Boseley*,  
 1139-40.  
 Aniline dyes in sweets and popcorn, *Voelcker*  
 1666-69.  
 Chromate of lead used to be found, *Hill*,  
 2485-86.  
 Now harmless, *Hill*, 2487-88.  
 Sweetmeats of red colour nearly always  
 coloured with rhodamine or analogous  
 colour, not a noxious substance, *Blyth*,  
 3369-70.  
 Charcoal used for sweets, *Cassal*, 3847.  
 Aniline dyes used, *Cassal*, 3847-48.  
 In one sample of sweets, 0.34 per cent. of  
 oxide of iron found, *Cassal*, 3847.

**CONFECTIONERY : Quantities.**  
 Amounts used, *Boseley*, 1049, 1064-70 (App.  
 No. 8, Table Q.).

## 97. COLOURING MATTERS—continued.

**DAIRY PRODUCTS :**  
 Annatto chiefly, an extract from the plant  
*Bixa orellana*, *Boseley*, 1050; *McCracken*,  
 2956-57.  
 Universal, but of limited variety, *McCracken*,  
 2954-55.  
 Aniline dyes no doubt used, *McCracken*,  
 2958-59, 2976-77, 2981-82, 2985-90, 3000,  
 3001.  
 Yellows used in harmless quantities, from  
 continent, Germany, or Holland, *McCracken*,  
 2978-80, 2998-99.  
 Aniline and annatto mixture used, *McCracken*,  
 2983-84.  
 Uniform colour desired, *McCracken*, 2960.  
 Colours not separated, *Blyth*, 3365-66.  
 Opposed by Central Chamber of Agriculture  
 by formal resolution, *Carrington Smith*,  
 4410-11, 4487.  
 Known to be used by 64 out of 100 circular-  
 ised farmers, *Carrington Smith*, 4474-76.  
 Should be prohibited; but little hurt to trade  
 would result, *Long*, 4685-86.

**DECLARATION :**  
 Would not lead to consumption of fruit in  
 natural state, *Copeman*, 1179-80.  
 In food should be made, save as to cheese,  
*Cameron*, 2587-91.  
 Would only harass trade; all trades should  
 be treated alike, *McCracken*, 2966-72, 3004.  
 Poisonous colours should be declared,  
*McCracken*, 2973-74.  
 Nature and amount should be stated, *Blyth*,  
 3435-37; *Brunton*, 7470.  
 Should be made; Crosse and Blackwell  
 declare them in some cases, *Blackwell*, 4878,  
 4898; and also of nature, 4899; and amount,  
 4900.  
 Might prevent fraud, *W. C. Williams*, 5350.  
 Should be made as to cocoa nibs coloured  
 by red oxides of iron, 5395-5400; and of  
 copper in peas, 5401.  
 Should designate poisonous colours as such,  
*Dupré*, 5921. This would go a long way,  
 5937.  
 They should be declared in butter, *Poore*, 7368.  
 All aniline dyes should be declared, 7398-99.

**DIGESTION, EFFECTS ON :**  
 Reference given to experiments, *Boseley*,  
 1071-73.

**FRANCE : Regulation :**  
 Strict, *Hudson*, 521-22.

**FRAUDULENT :**  
 "Smokine" described, *Hope*, 6849. Use  
 fraudulent, 6849-51. Glucose and treacle  
 sold as syrup also fraudulent and burnt  
 sugar and dilute acetic acid when sold as  
 vinegar, 6851. Latter not injurious. Col-  
 ouring matters conceal staleness, inferiority  
 and dirt, 6852. Colourings of "egg-pow-  
 ders" fraudulent, 6863, 6866.

**HARMLESS :**  
 Not objected to in butter, cheese, confec-  
 tionery, and general fancy goods, *W. C.*  
*Williams*, 5350, 5385-87.  
 Not objected to, *Dupré*, 5931, but proof of  
 character should precede use, 5932.  
 Sometimes ornamental and harmless, *Hope*,  
 6847-48.

**HEALTH :**  
 Should not be sacrificed to colouring matters,  
*Hill*, 2483.

**INJURIOUS :**  
 Should be scheduled for all produce, *Blyth*,  
 3360-61, 3371-75.  
 Weyl holds picric acid, dinitrokresol, Martius'  
 yellow, Bismarck brown, orange II., and  
 metanil brown, to be injurious, *Blyth*,  
 3358.  
 Injurious properties could be determined by  
 long experimentation on animals, by mul-  
 tiple persons, *Blyth*, 3398, 3412.  
 Salts of copper, picric acid, and impure  
 aniline dyes occasionally used, *Blyth*, 3417,  
 18.

## 97. COLOURING MATTERS—continued.

## INJURIOUS—continued.

Dinitrokresol would presumably derange a child's digestive organs, *Blyth*, 3420.  
 Not met with now, but Dr. Campbell Brown has found lead chromate in sugar oranges and lemons, *W. C. Williams*, 5387-90.  
 Not come across, *Atfield*, 6570-71. Common knowledge that some harmful substances are used, 6572.

## IRON SALTS:

Not well known, *Boseley*, 1107-11, 1118-27.

## JAMS:

Complete list, *Boseley*, 1049, 1064-70 (App. No. 18).

In dark coloured jams, majenta, or fuchsine, *Boseley*, 1063, 1148-51.

Apricot, yellow jams, and marmalade seldom coloured, *Boseley*, 1063.

Not requisite, *Boseley*, 1080.

Improve appearance, *Boseley*, 1081.

None used by Messrs. Keiller, *Boseley*, 1142-43.

Used, *Copeman*, 1231.

Heard of, as found, *Voelcker*, 1666-69.

By cochineal extract, only colouring known, *Blackwell*, 4879, in small quantity and harmless, giving uniformity of colour, 4880-83. Public demand a pleasing looking article without question of process adopted, 4891, being quite indifferent thereto, 4891-95.

Unknown red dye found, *W. C. Williams*, 5361.

## JAMS: Quantity:

Amounts used, *Boseley*, 1049, 1064-70 (App. No. 8, Table Q.).

## JELLIES:

Coloured with small quantities of colouring, chiefly yellows and reds, *Fisher*, 4793-94.

## MAGENTA:

Health of workers not affected, *Boseley*, 1074, 1145-47, 1164.

Never tested, *Boseley*, 1152-58.

## MARGARINE:

Usually fraudulent, *Voelcker*, 1692; *Cassal*, 3838-41.

To meet demand and resemble butter, *McCracken*, 2963-65; *Brierley*, 3280.

Matter behaving like methyl orange commonly used for margarine, *Brierley*, 3279.

By the trade neither honest nor desirable, *Hattersley*, 5806-13; does not hurt the Aylesbury Dairy Company's butter trade, 5814.

## MARTIUS' YELLOW:

Rarely used, *Boseley*, 1112-14.

Poisonous, *Boseley*, 1115.

Never known in butter, *Boseley*, 1116.

Used in small quantity in macaroni, *Blyth*, 3358, 3362-64.

Never detected, *Hegner*, 5571.

## MEAT:

Red dyes found, *W. C. Williams*, 5362-66, 5370, 5377-78.

## MEAT EXTRACTS:

Red ochre used in bloater pastes, and German sausage skins sometimes dyed, *Fisher*, 4771, 4775-71.

Nitrites not poisonous as used for meats, *Fisher*, 4771.

## METALLIC:

None used by Messrs. Keiller, *Boseley*, 1074.

No arsenic or lead in those used by Messrs. Keiller, *Boseley*, 1074.

## MILK:

Annatto, in aqueous solution, *Boseley*, 1050.

Annatto as used quite insufficient to flavour milk, *Boseley*, 1051.

Aniline dyes becoming more general, *Boseley*, 1098-1100.

No excuse for *Voelcker*, 1691, 1748.

## 97. COLOURING MATTERS—continued.

## MILK—continued.

Aniline colours used at times, *Hill*, 2485-86.

Annatto and possibly turmeric used, *Hill*, 2485-86.

Now harmless, *Hill*, 2487-91.

Not known in Southampton, annatto freely used years ago, and no bad results heard of, *Brierley*, 3282-86.

Fraudulent, *Cassal*, 3842-43.

Aniline dye used, *Cassal*, 3844.

Might be an offence, as fraudulent, *W. C. Williams*, 5351-52, 5420-21.

London milk almost invariably coloured, *Hegner*, 5572-75, deceptive, but universal, practice, 5573.

Do not rise in the cream, but remain in the skim milk, *Richmond*, 5862-63.

Complaints have been made of milk of excellent quality because uncoloured, *Richmond*, 5870-71.

Colouring matter used by Aylesbury Dairy Co., to secure continuity of colour all the year round, *Hattersley*, 5802, 5804-5. Would be glad to be able to do without it, 5802, in milk, 5815. Customers demand coloured milk, but little colour used in summer, 5803, and will have it, 5857-60. Repeated attempts to do without colouring milk have failed, 1861. Complaints have followed its temporary disuse, 5866-69.

There is annatto in most milk, *Sorensen*, 7083.

Colouring of milk caused dyspepsia in an infant, *Halliburton*, 7538.

## OXIDE OF IRON:

Found in cocoa, *Boseley*, 1130-37.

May have been added to cocoa as an ochre, *Boseley*, 1138.

Found in a sample of sweets, *Cassal*, 4847.

Known to be used, *Fisher*, 4780.

## PEPPER:

Used, doubtless harmless, *W. C. Williams*, 5247-49.

## PHYSIOLOGICAL EFFECTS:

Aniline yellow and methyl orange produce undesirable symptoms, *Long*, 4684.

## PICKLES:

Red cabbage, 4 ozs. sulphuric acid to 40 gallon barrel, *Boseley*, 1056-60.

Piccalilli, 3 lbs. turmeric to 40 gallon barrel, *Boseley*, 1056-60.

Not coloured, *Hill*, 2484; for many years, *Blackwell*, 4885.

Derivatives never found, *Richmond*, 5765.

## POISONING:

Case by dinitrokresol recorded by Weyl, *Blyth*, 3360, 3396-97.

Iron and oxide of iron not usually classed as poison and poisonous salts, *W. C. Williams*, 5394.

Colouring matters of a poisonous nature should not be employed, *Dupré*, 5913, in any quantity, 5914. Colours should be classified, 5918, and poisonous colours entirely prohibited, 5919.

## PRESERVATIVES:

Some meat preservatives coloured, *Fisher*, 4772-74.

## PROCEEDINGS:

No experience as to legal dealings with injurious colourings, *Hill*, 2494-95.

## PROHIBITION:

In milk urged, *Voelcker*, 1691, 1748; *Cameron* 2592.

Not advocated in butter, *Voelcker*, 1691 *Cameron*, 2594-95.

Specified metallic colourings prohibited in certain countries, as Belgium and France, and should be at home, *Hill*, 2496-98.

Would close some markets to Scotland for cheese, *McCracken*, 2961.

Needed as regards certain coal tar derivatives, *Brierley*, 3290-94.

## 97. COLOURING MATTERS—continued.

## PROHIBITION—continued.

Weyl advised in Germany as to certain colours, *Blyth*, 3358; and certain colours, including picric acid believed to be prohibited there, 3359.

Should be absolute as to injurious matters, e.g., sulphate of copper in vegetables, ferruginous earthy matters, oxide of iron, and inferior aniline dyes in sweets, *Cassal*, 3844-46.

Desired as to dairy produce by Central and Associated Chambers of Agriculture, *Carrington Smith*, 4487, 4554-57.

Desired by Staffordshire Chamber of Agriculture as to milk and margarine as being fraudulent, *Carrington Smith*, 4488-4503.

Might temporarily restrict milk supply, and raise prices for a short time, *Carrington Smith*, 4413-14, 4549.

Should be effected in dairy produce, *Long*, 4685-86.

Colouring of milk should not be allowed, *Long*, 4961, 4968, because fraudulent, 4962. Not believed in for butter, 4963, nor for cheese, 4964-67. Should not be allowed in cream, 4968, or butter, or margarine unless it be very distinctively tinted, 4969, to prevent fraud, 4970.

Of fraudulent colouring as of "mixtures" and the like, advocated, *Dupré*, 5938-41.

Prohibition of colouring of butter would lead to seasonal changes in natural colour and give dissatisfaction, *Gibson*, 6365.

Colouring matters should not be used; such use is provocative of danger, *Poore*, 7368.

Better to avoid artificial dyes, *Halliburton*, 7539; public taste known to be arbitrary, 7540.

## RESTRICTION :

Control a difficult problem, scheduling might be adopted, *W. C. Williams*, 5384-85.

## SAFFRON :

Used, and non-injurious, *Copeman*, 1178.

## SAUSAGES :

Colouring used, including rose pink, *Tubb-Thomas*, 4973.

Red dyes found, *W. C. Williams*, 5362-66, 5370, 5377-78.

Commonest used described, *Hope*, 6647-48.

## SPICES :

Used, doubtless harmless, *W. C. Williams*, 5347-49.

## SUGAR :

Imitation Demerara occasionally treated with aniline dyes, *Boseley*, 1117; *Hill*, 2485-86.

Sometimes fraudulently coloured, *Cassal*, 3844, 3850.

Aniline dyes used, *Cassal*, 3847-48.

Caramel only should be present; and it does not dye, *Cassal*, 3849-50.

## SULPHUR :

Used for bleaching raisins, apricots, plums, &c., *Copeman*, 1172.

Keeps fruit a good colour, and sometimes used for flavouring it, *Copeman*, 1173.

Not known to be harmful as used, *Copeman*, 1173.

Added to bloom of Carlsbad plums, *Copeman*, 1174-76.

Small amount used in champignons, *Copeman*, 1174-76.

Coloured goods generally preferred and demanded, *Copeman*, 1280-81.

## SULPHURIC ACID :

Not known in jams and preserved fruit, *Copeman*, 1177.

## TEA :

None found, *W. C. Williams*, 5379.

## TURMERIC :

Used in piccalilli, &c., and non-injurious, *Copeman*, 1178.

## VEGETABLES :

Such vegetables fairly well used *Copeman*, 1181-82.

## 97. COLOURING MATTERS—continued.

## VEGETABLES—continued.

Mostly free, *Hill*, 2481-82.

Those not coppered less green, *Hill*, 2483.

Bright green, found to contain aniline dye, *Blyth*, 3356.

## WINE :

Grape juice sufficiently colours, *Blyth*, 3354.

Not coloured on any scale; one sample of Burgundy contained colouring like fuchsine, *Blyth*, 3413-15.

Liqueurs not examined, *Blyth*, 3416.

Colouring matters, other than grape juice, not needed in wine, *Gilbey*, 4361. "Colour wine" used, but little colouring matter, 4387, 4393. Alum not known, 4388. Probably burnt sugar and glucose in liqueurs, 4389. Salts of copper, picric acid, or cochineal not known, 4390-91. No excuse or need for colourings even in cheap wines, 4394-95. Messrs. Gilbey's wines tested for colouring matters, 4396-4403 and footnote.

## ZINC COMPOUNDS :

Believed to be added to peas, *Boseley*, 1128-29.

## 98. COPPER IN FOODS :

Copper in foods not natural to peas, *Copeman*, 1220.

Present naturally in beans, *Copeman*, 1220.

No ill-results known, *Brierley*, 3289.

Found in peas, flour, bread, tobacco, and ash of lime trees, *Blyth*, 3377.

Held to be natural to peas, *Blyth*, 3391-95.

French preserved beans supposed to be coppered, *Blackwell*, 4876.

Found only in very minute amounts in vegetables and jams as regards a particular firm, and inference drawn of accidental admixture by method of manufacture, *Attfield*, 6573.

Copper accidentally in canned foods, apart from its use as a colouring agent, *Halliburton*, 7534-38.

## POISONOUS PROPERTIES :

Wrong to use a strong poison to simply colour food, *Blyth*, 3434.

## PROHIBITION :

In Germany, *Copeman*, 1233.

Should be entire, *Cameron*, 2557.

## USES :

For greengages in France, *Copeman*, 1178.

To preserve colour of peas, *Vasey*, 2016.

## FOREIGN LAW AND PRACTICE : France :

No restriction as to peas, *Copeman*, 1193-94 (App. No. 21).

## Germany :

Copper sulphate in peas held in Germany to be harmless in amount required, *Grimbaum*, 6448-49; and not prohibited in minute quantities, 6450-51. Laws of other countries not known, 6452-56.

## Italy :

Quantity used in peas, in parts of country, 10000, *Copeman*, 1191.

## Switzerland :

Quantity used in peas, in parts of country, 10000, *Copeman*, 1191.

## MEDICINAL USE :

Doses, *Copeman*, 1260, 1299, 1302.

Pharmacopoeial dose of sulphate of copper from  $\frac{1}{2}$  to 10 grains, *Blyth*, 3430-31.

## PEAS :

Subject not well known, *Boseley*, 1107-11, 1118-27.

Uneatable if strongly coppered, *Copeman*, 1260-66, 1296.

## PEAS : Analyses :

Made in France, *Copeman*, 1215, 1217-18.

Quantitative, not trusted, *Copeman*, 1256-5.

Of whole lb., desirable, *Vasey*, 2006.

Show copper as an organic salt of copper, *Cameron*, 2552.

Method of detection at fault, *Blyth*, 3378-91.

About 2½ oz. examined, from well-shaken sample, *W. C. Williams*, 5341-42.

98. COPPER IN FOODS—*continued.*

## PEAS : Colour :

Fairly bright green, *Copeman*, 1290.  
 Not known to go off, *Copeman*, 1296.  
 Preserved as natural, but old peas not used, *Bannister*, 3561.  
 Recovered, *Bannister*, 3570.  
 Colouring not lost, *Bannister*, 3571-72, 3575-80.

## PEAS : Complaints :

Unknown from London clubs, &c., *Copeman*, 1292.

## PEAS : Declaration, Simple :

Labelling alone required in certain American cities, *Copeman*, 1191.  
 Labelling alone requisite, *Copeman*, 1222.  
 Labelling not necessary in many cases, *Copeman*, 1229.  
 Sufficient, *Vasey*, 2026-27.  
 Would seldom meet consumer's eye, *Bannister*, 3592-93.  
 No objection to, *Bannister*, 3592, 3594, 3596.  
 Made in Pennsylvania, *Bannister*, 3595.  
 Should be made, *W. C. Williams*, 5401.

## PEAS : Declaration, Quantity :

Actual amount, known to be stated in America, *Copeman*, 1222.  
 No objection, *Copeman*, 1223-28, 1303-4; *Vasey*, 2094-96; *Bannister*, 3597.  
 Difficult, *Blyth*, 3436-37.  
 Should be specific, *Poore*, 7407-11; *Brunton*, 7469.

## PEAS : Demand :

Public will have green peas, *Copeman*, 1283-84, 1286-88; *Bannister*, 3573-74.  
 In every restaurant in Ostend, and in common use in Belgium, *Copeman*, 1289.  
 Would not habitually eat coppered peas, and would warn patients against them, *Cameron*, 2599.  
 People would avoid knowingly eating them, *McCracken*, 2975.  
 Command a large sale, *Bannister*, 3560.

## PEAS : Distribution :

Not always even, *Copeman*, 1258.  
 Unknown, *Vasey*, 2014; *Bannister*, 3599-3600.  
 Likely to be mostly outside, *Vasey*, 2015.  
 Absolute uniformity not expected, though found, *Vasey*, 2019, 2024-25, 2028-29.  
 Probably general, and by some deemed to be associated with chlorophyll of pea, tending to its concentration outside the pea, *Bannister*, 3600-5.  
 Method of adding not known, *Blackwell*, 4896.  
 Found in interior of peas, *W. C. Williams*, 5343.  
 Unequal distribution in peas should hold manufacturer liable if fixed amount for whole be exceeded in any one portion, *Brunton*, 7471-72.

## PEAS : Keeping Quality :

Unknown with  $1\frac{1}{2}$  grains of copper sulphate per lb. of peas, *Copeman*, 1268-69, 1272.  
 No objection to experiments being made, *Copeman*, 1270.

## PEAS : General Physiological Effects :

Of 6 grains per lb., unknown, *Vasey*, 2008.  
 Must determine its use, *Vasey*, 2018.  
 Copper not a constituent of the body, *Mann*, 2621.  
 Solubility in human economy or gastric juice doubted, *Blyth*, 3428.  
 Copper albuminate not dissolved during digestion, *Bannister*, 3581-86.  
 Not known, *Bannister*, 3606-7, 3614-18.  
 Copper sulphate used as an astringent in doses under one grain, *Bannister*, 3613.  
 Effects of copper, in unsatisfactory position, *Fisher*, 4781-82.  
 About 40 per cent. of copper in peas enters the stomach in a soluble form, *W. C. Williams*, 5372-76.  
 Effect of 1 grain per lb. of peas unknown. Some people idiosyncratic to minute quantities, *Dupré*, 5922-25; and idiosyncrasy is very common 5926-30.

98. COPPER IN FOODS—*continued.*

## PEAS : General Physiological Effects.

Copper as found in peas held to be soluble in human economy, *Hope*, 6930; on eminent hearsay evidence, 6931. Uneasiness and indigestion have resulted from coppered peas, 6932.

Copper sulphate in peas will probably enter into combination with proteid constituents. Action of copper is very largely on the intestines, *Starling*, 6981-82. Is opposed to small amounts of copper for colouring peas, 6983. Would be dangerous taken constantly in  $\frac{1}{2}$  grain to lb. of peas, 6984-85.

Held to be soluble in the human body, *Poore*, 7400-2.

Harmfulness of copper in peas depends on quantity used, *Halliburton*, 7554.

## PEAS : Affirmed Physiological Effect :

Dangerous to add  $7\frac{1}{2}$  grains of metallic copper per lb., *Vasey*, 2093.  
 Copper in any quantity likely to be highly deleterious, *Womack*, 7510-12.

## PEAS : Negative Physiological Effects :

No case of poisoning known, *Copeman*, 1197, 1201-3, 1263, 1274, 1297-98 (App. No. 22).  
 Illness unknown, *Copeman*, 1198.  
 Experiments made lead to inference that the digestive system may dissolve the copper, but Professor Fraser's experiments differ, *Cameron*, 2549-51.  
 No ill-results known, *Brierley*, 3288; *Bannister*, 3587-89, 3608-11.  
 A certain undefined amount would not be injurious, *Blyth*, 3421-22.  
 No physiological result anticipated from 5 grains per lb. of peas, *Blyth*, 3426-27, 3429, 3433.  
 No injury to health from  $\frac{1}{2}$  grain per lb., *W. C. Williams*, 5417.  
 Copper in minute doses quite innocuous, *Brunton*, 7468.

## Poisonous Quality :

Proof difficult, *Copeman*, 1264.  
 Not very strong, *Copeman*, 1259.  
 Copper a poison, to some extent cumulative, but not quite like lead, *Cameron*, 2533, 2553-54, 2556, 2600.  
 A slow poison, with delayed results never definitely traced, *Cameron*, 2553.  
 No cases of poisoning known, *Cameron*, 2556.  
 Copper produces chronic poisoning, *Mann*, 2621.  
 Occasional doses could not be proved harmful, *Mann*, 2622.  
 In large quantities, but not known to be cumulative, *Bannister*, 3590-91.  
 Copper sulphate a known poison, *Cassal*, 3846.  
 Copper is injurious to health, and along with its salts is poisonous, *W. C. Williams*, 5393.  
 Copper in peas a poison, perhaps not injurious in quantities used, but use fraudulent, and should be prohibited, *Hehner*, 5628; limit of safety not so easily overstepped as with some poisons, 5629; but copper sulphate has a point where it becomes distinctly poisonous, 5630.

## Proceedings :

Medical evidence in litigation cases considered important, *Copeman*, 1305-6.  
 Taken in Southampton years ago, *Brierley*, 3287.  
 None taken in Birmingham, *Hill*, 2492-93.

## Prohibition :

Would ruin the trade, *Copeman*, 1285.  
 Was in France, but withdrawn, *Vasey*, 2088-89.  
 Should be effected, *Mann*, 2621; *Cassal*, 3844-46; *Stevenson*, 4841; *Hehner*, 5628; *Dupré*, 5915, 5917.  
 Not necessary, as used in France, *Bannister*, 3560.  
 Prohibition of copper in peas desired, *W. C. Williams*, 5358, 5416; and if not so, should be strictly limited, 5359. Peas probably unsaleable if not greened, 5360, 5368.  
 Copper in peas indefensible, *Poore*, 7370; in any quantity, 7371-72, 7403-4.

98. COPPER IN FOODS—*continued*.

Prohibition—*continued*.

Copper in peas to be condemned, *Halliburton*, 7555, 7557; as a foreign substance, and cumulative; no copper normally in the human body, 7556. But no experiments made by witness, 7595-96. Cumulative effects likely to become increasingly harmful, 7597-7600.

Quantity found:

Of metallic copper in France, *Copeman*, 1209-14 (App. No. 20).

Larger than in other vegetables, *Copeman*, 1219-21.

Six grains per lb., *Vasey*, 2005, 2007, 2097.

Difficulty of defining, *Vasey*, 2019-21.

Some 4 to 5 grains per lb., *Blyth*, 3423-25.

Diminishing, *Stevenson*, 4840; *W. C. Williams*, 5337-40, 5344-46.

Has found  $\frac{1}{2}$  grain per lb. in peas quite green. Interior of peas found to contain copper, *W. C. Williams*, 5343.

Quantity, Maximum:

Fixation advocated, *Copeman*, 1199, 1200, 1206-8, 1285.

Desired, about 2.7 grains of copper sulphate per lb., *Copeman*, 1215-16.

Above amount used in Kent, *Copeman*, 1266.

Should be determined, *Vasey*, 2022-23.

Too much would spoil the peas, *Bannister*, 3597.

Most found,  $\frac{1}{1000}$ , and  $\frac{1}{7700}$  regarded as a fair average by French Government, *Bannister*, 3598.

About  $\frac{1}{1000}$ , or 2.9 grains of commercial copper sulphate per lb. of peas would be safe, *Bannister*, 3612.

Quantity, Minimum:

Requisite, about two grains per lb., *Copeman*, 1240-43, 1253-56.

Minute quantity suffices, *W. C. Williams*, 5369, 5380-83.

Copper not uncommon in bottled peas, fruits, and vegetables;  $\frac{1}{2}$  grain to a lb. deemed by trade necessary to green the peas, *Hope*, 6929.

RESTRICTION:

None in France, *Copeman*, 1193-94 (App. No. 21).

To one grain per lb. would be impracticable, *Copeman*, 1267.

98. COPPER IN FOODS—*continued*.

RESTRICTION—*continued*.

Foreign laws have changed, 52, 1271.

Use requires vegetable, 5337-40, 5344-46.

Use:

To preserve

*Williams*, 5337-40, 5344-46.

Not universal

Frequently found

Probably found

Objectionable on grounds

4787.

Fraudulent, *Fisher*, 4788-92; 5403-15, 5420-27; *Poore*, 7405-6.

Supposed to be used in foreign preservation

*Crosse & Blackwell* have sold uncoloured

peas; not large trade; no demand here;

large export trade, *Blackwell*, 4876-77.

French peas coppered abroad, *Blackwell*, 4901.

Ceased some years back, in force again, to

meet public demand, *Dupré*, 5916.

Scarcely fraudulent, *Dupré*, 5933-36.

COPPER SULPHATE:

An injurious colouring agent, *Hill*, 2484.

Not present as such in peas, *Vasey*, 2009-13, 2086-87; *Bannister*, 3619-25.

COPPER SULPHATE: Uses:

For peas, beans, spinach, and mixed vegetables, *Copeman*, 1183.

Above goods unsaleable unless greened, *Copeman*, 1184-87.

Copper in peas not present as a sulphate, but as an insoluble proteid compound, possibly soluble at times, *Vasey*, 2009-13, 2086-87.

COPPER SULPHATE IN PEAS: Quantity used:

From 2 to 2.8 grains per lb., *Copeman*, 1190.

In parts of Switzerland and Italy,  $\frac{1}{1000}$  *Copeman*, 1191.

COPPERED VEGETABLES:

Copper found in many, and in all of French origin, *Blyth*, 3357, 3376.

Copper a natural constituent, though fact disputed by a French chemist, *Blyth*, 3357, 3376, 3387-91.

Foreign preserved vegetables supposed to be coppered, *Blackwell*, 4876.
